PREFACE

This publication contains input-output tables for 1989-90. The tables are also available on floppy disk. Input-output tables are part of the Australian national accounts, complementing the quarterly and annual series of national income, expenditure and product aggregates. They provide detailed information about the supply and disposition of commodities in the Australian economy and about the structure of and inter-relationships between Australian industries.

With the release of tables for 1989-90, the ABS has completed 13 input-output tables for Australia. They are for reference years 1958-59, 1962-63, 1968-69, 1974-75, for each year from 1977-78 to 1983-84, 1986-87 and for 1989-90. Commencing with the 1974-75 tables, an estimation methodology involving a combination of clerical and mathematical estimation techniques was introduced and it has been used in compiling the current tables.

The publication *Australian National Accounts, Input-Output Tables (Commodity Details)* (5215.0) will be released for 1989-90 shortly. It will provide details of the classification of goods and services used in the compilation of input-output tables (the Australian Input-Output Commodity Classification (IOCC)). A concordance between items of production, imports and exports will be included.

The publication *Australian National Accounts, Input-Output Multipliers* (5237.0) for 1989-90 will also be released shortly.

EXPLANATORY NOTES

Introduction

This publication contains comprehensive results of the 1989-90 input-output project. All major tables in this publication are presented on microfiche which are located in an envelope inside the front cover. In addition, a selection of tables identified on the contents page is provided as printed copy. Most data contained in this publication (5209.0), plus eleven margin matrices, are also available on floppy disk. Details of this floppy disk and an order form are included in Appendix F.

2. The industry classification used in this publication is similar to that used in the 1986-87 input-output tables. Generally, the definitions and estimation procedures follow those used for 1986-87 which are described in detail in Section 19 of *Australian National Accounts, Concepts, Sources and Methods* (5216.0).

3. The 1989-90 input-output tables are the 13th in the series. An overview of earlier tables is provided in the paper *Systems for the Compilation of Australian Input-Output Tables*, published in the 1988 issue of the Australian Journal of Regional Science. Employment by industry (Table 22) is presented in this publication for the first time. The table contains estimates of employment derived from Labour Force Survey and Population Census data.

4. These input-output tables have been produced using the input-output methodology introduced for the compilation of the 1974-75 tables. It involves estimating from basic data sources the summary aggregates (industry output, primary inputs and final demand) and then estimating intermediate inputs from the preceding tables in the series using a mathematical estimation technique to optimally satisfy the accounting constraints imposed by the summary aggregates. In input-output literature, this estimation technique is referred to as the RAS method. Estimates provided by the simple application of the RAS method are modified in two ways. First, each intermediate flow is modified, after reference to economic censuses or similar data sources according to a rotating program. Second, in the intervening years, estimates provided by the simple application of the RAS method are improved upon, wherever possible, by reference to economic censuses or similar data sources. The modifications made to the initial RAS-based estimates, as well as involving the separate estimation of selected inputs using basic data, involve the re-estimation of the remaining intermediate inputs, again using the simple RAS method. Potentially, all the remaining intermediate inputs may be changed as a consequence of modification. Highly disaggregated working matrices are used in the application of the modified RAS method to the compilation of the tables. The modified RAS method is applied to working matrices with 109 industries and approximately 1300 commodities. (Because of confidentiality and other data considerations the final working matrices are aggregated to contain 109 commodity groups for publication.) Appendix A to this publication illustrates the RAS method and a paper is

available in which the method and its application are discussed in detail (see paragraph 120).

5. The tables compiled according to the Australian input-output methodology provide a useful reflection of the structure of the Australian economy for the year in respect of which they are compiled. Nevertheless, care should be taken in interpreting the tables in this publication and in analysing year-to-year movements in flows and coefficients, particularly in the context of detailed industry or commodity analysis. Discontinuities in time series can occur because the input-output tables for earlier years are not revised to reflect the latest source data available.

6. In the last three decades, there has been considerable development in input-output statistics. Input-output tables are now compiled in all statistically advanced (and many less advanced) countries and are being used in a variety of applications. They can be used in complex mathematical models of the economy but they can also be of considerable benefit to non-economists who may refer to them to obtain information on the economic structure of the country and an appreciation of the interdependence of various parts of the economy. There are many publications available that deal with aspects of input-output techniques in a more exhaustive and systematic way than would be possible here. A comprehensive list of such publications is maintained and occasionally updated by the United Nations Statistical Office. The most recent is *Input-Output Bibliography*, 1966-70, UN Statistical Papers, Series M, No. 55. The relationship of input-output to other parts of national accounts is described in *A System of National Accounts*, UN Studies in Methods, Series F, No. 2, Rev. 3. An excellent description of the concepts, methodology and applications of input-output statistics may be found in *Input-Output Tables and Analysis*, UN Studies in Methods, Series F, No. 14, Rev.1. Other recent collections of input-output tables are: *National Accounts Statistics*; *Study of Input-Output Tables, 1970-80*, UN 1987, and *Input-Output Tables for Developing Countries* (2 Vols), UNIDO, 1985, and *National Accounts ESA Input-Output Tables 1980*, Eurostat, 1986.

Basic structure of input-output tables and their relationship to other national accounts

7. The structure of the Australian input-output tables and their relationship to the Australian national income, expenditure and product accounts are described in the latest edition of the publication *Australian National Accounts: Concepts, Sources and Methods* (5216.0), released in May 1990.

8. The 1989-90 input-output tables have been compiled in terms of 109 industry sectors. The 109 sectors in the first quadrant of the large tables have been aggregated to form smaller tables with 28 sectors, as shown in Appendix C. Although the sectors in the small tables are not as homogeneous as those in the larger tables, it is expected

STRUCTURE OF AUSTRALIAN INPUT-OUTPUT TABLES

NOTE: This structure corresponds to the format adopted in Tables 5-7 and 11-13 of this publication. Variations in format are explained in paragraphs 7 to 40.

The shaded areas correspond to aggregates shown in the National production account.

corresponds to aggregates shown as the components of 'gross domestic product' at market prices.

that the aggregated tables will be more convenient for some purposes, and will enable users to gain an appreciation of the essentials of input-output tables.

Basic matrices

9. Regardless of whether commodities or industries are used to define the sectors, the initial assembly of data is the same. It is necessary to record the commodity flows in the economy in a way suitable for input-output analysis. A system of building blocks is used, each of which shows, for a commodity (or, more commonly, a combination of commodities):

- its origin, or source of supply, divided into local production from various industries, and imports;
- its destination, classified into usage by various industries and final demand categories;
- the difference (or margin) between the basic value and the purchasers' price of each commodity.

10. Recording supplies by industry of origin does not present any difficulty apart from the necessity to classify imports in the same way as locally produced commodities. The destination of commodities is more difficult to determine. The first requirement is information on the usage by each industry and final demand category, both in total and for the constituent commodities. Although the using industries can supply information on the nature of their inputs, the descriptions may be broad and may differ from descriptions used by the suppliers of the same commodities. Where the information is not available in sufficient detail it must be estimated.

11. Once these building blocks are ready they are arranged into four basic matrices. The first of these is the *make matrix* (Table 1) which shows output of local industries in the columns and output of commodities primary to these industries in the rows. Characteristically, the largest entries are on the main diagonal because an industry produces mainly commodities primary to it. This matrix provides insights into the way the production of commodities by industries is organised. The columns of the matrix show, for each industry, the composition of its output in terms of commodities (or the industry product mix as it is sometimes called) and the extent to which each industry specialises in the production of commodities primary to it. The ratio between the production by an industry of commodities primary to it and its total output is called the *specialisation ratio*. The rows of the matrix show how the production of each commodity originated from the various local industries. Dividing each entry in a row by the row total gives the market shares of industries which produce the commodity. The largest market share is given by the ratio of the diagonal entry to the row total. This is called the *coverage ratio* which is the market share of the industry to which the commodity is primary.

12. The specialisation and coverage ratios measure the homogeneity of industries. If both ratios are 100 per cent, there is an identity of industry output and supply of the commodity from domestic production (i.e. there is no

secondary production and inputs and outputs are perfectly symmetrical). In practice, ratios of 100 per cent are rare and the available data have to be manipulated in order to minimise the problems posed by the existence of secondary production and to produce estimates of input and output which can be more usefully related to one another. This can be achieved by combining narrowly defined industries to reduce the extent of secondary production. It can also be achieved during the estimation of commodity flows by a process known as *redefinition* which means shifting some secondary production, together with the relevant inputs, from the industry where it was produced to the industry to which it is primary.

13. The second basic matrix, which is commonly referred to as the *absorption matrix* (Table 2), has commodity groups and primary inputs in its rows, and using industries and final demand categories in its columns. The rows of this matrix record the total supply of commodities, whether locally produced or imported, and show how these commodities are absorbed by industries as intermediate inputs to current production and by final demand categories. Further down, the rows designated by prefix *P* show the primary inputs which have been purchased by industries and by final demand. Reading down the columns one can find the composition of inputs (intermediate and primary) into each industry and composition of each final demand category. Therefore all flows of goods and services in the economy are covered.

14. The third basic matrix is the *imports matrix* (Table 3) which shows in the rows the industries to which the imported commodities would have been primary had they been produced in Australia, and in the columns the usage of these commodities by industries and final demand categories. This dissection is shown only for competing imports, i.e. those commodities which are both produced locally and imported so that substitution between the two sources of supply is possible. It is not shown for complementary imports which, by definition, are of a kind not produced in Australia; nor for re-exports which are goods imported into Australia and then exported without having been used or transformed in any way. These are recorded in separate rows rather than in the rows of industries to which they would have been primary if they had been produced in Australia.

15. The fourth basic matrix is the *margins matrix* which shows the difference between the basic value and purchasers' price of all flows in the absorption matrix. The margins matrix is the sum of separate matrices for each type of margin (for example, commodity taxes (net), wholesale, retail). The component margins matrices are not included in this publication but are available on floppy disk; Table 4 in this publication provides a summary of the margins matrices.

16. These four basic matrices are simply a record of the estimated flows of goods and services in the economy. However, the absorption matrix is not symmetrical, which makes it unsuitable for some analytical purposes. It can be made symmetrical by reorganising it so that both rows and

columns refer either to industries or to commodities. In the first case, rows of the absorption matrix have to be adjusted to show industries purchasing industry output rather than commodities. In the second case, columns of the absorption matrix have to be adjusted so as to show inputs relevant to the production of commodities. These adjustments lead to symmetrical flow tables which are either industry-by-industry or commodity-by-commodity tables. Only industry by industry tables have been prepared for this publication.

Special treatments adopted in compiling input-output tables

17. The content and meaning of the tables depend also on some other aspects of compilation, particularly:

- treatment of intra-industry transactions;
- allocation of imports;
- valuation of transactions.

There are various methods available for dealing with each of these and there are several types of tables which can be prepared from the same basic data.

Treatment of intra-industry transactions

18. Depending on the treatment of intra-industry transactions the output of an industry can be defined in three different ways according to whether, and to what extent, these transactions are counted as part of the output.

19. The output of an industry can be defined as the total value of all flows of commodities produced by the establishments classified to the industry. All intra-industry flows are included as output when it is defined in this way. For example under this definition, the output of the *motor vehicles and parts and transport equipment n.e.c.* industry (32.01) would consist not only of fully assembled vehicles but also of motor bodies, engines and other components despatched from (or added to stock by) any unit recognised as an establishment for statistical purposes. This definition of output disregards the fact that many of these components will have been incorporated in finished motor vehicles and therefore will have been counted twice. Output calculated according to this definition could be as much as twice or three times the value of finished products of the industry.

20. Another possible definition of the output of an industry confines output to commodities produced by establishments within the industry and sold outside the enterprise. This definition, too, results in some duplication because the components manufactured and sold by one enterprise are all counted separately although they may have been used in a finished product of another enterprise in the same industry and counted again in the value of this product. Moreover, the components despatched from one establishment could be omitted entirely or counted either partly or wholly depending on whether they were used by another establishment of the same enterprise or by a different enterprise.

21. Finally, the output of an industry can be defined as net of all intra-industry transactions; i.e. excluding not only the transfers between the establishments in industry i belonging to the same enterprise but also all flows between establishments in industry i belonging to different enterprises. If this definition of output is used, the input-output table is said to be *net* and the main diagonal is empty. If one of the other definitions is used the table is *gross* and there are entries on the main diagonal.

22. For 1974-75 and subsequent tables, intra-industry flows are included in the tables, which means that the estimates of output can be directly compared with other information about an industry. A further consequence of recording intra-industry transactions is that the level of output is unaffected by the number of industries used (that is, by different levels of industry aggregation).

Allocation of imports

23. There are various ways available to record imports in input-output tables. The main ones are:

(a) *Direct allocation of imports* which involves allocating all imports directly to the sectors which use them. For example, imported raw tobacco is allocated to the *tobacco products* industry (22.01) and, together with other imported materials used in manufacturing tobacco products, is recorded in row P6 of column 22.01. In this case, all flows recorded in Quadrants 1 and 2 refer only to the use of local products and consequently Quadrant 1 does not reflect the technological input structure of the industry.

(b) *Indirect allocation of imports*, which involves first recording all imports as adding to the supply of the sector to which they are primary and then allocating this supply along the corresponding row of the table to using sectors. For example, imported raw tobacco is allocated to the *other agriculture* industry (row P6 column, 01.06) and both local and imported raw tobacco flow into the *tobacco products* industry (row 01.06, column 22.01). The result is that flows in Quadrants 1 and 2 contain imported and locally produced commodities without distinction. Quadrant 1 then better reflects the technological input structure of the industry and Quadrant 2 better reflects the commodity composition of final demands.

(c) *Direct allocation of complementary imports and indirect allocation of competing imports*. This method involves first distinguishing between complementary and competing imports and then allocating the first group directly and the latter indirectly. For example, imported raw tobacco is a competing import and is indirectly allocated to the *other agriculture* industry (01.06), but natural rubber, a complementary import, is allocated directly to the *rubber products* industry (row P6, column 34.02).

Each of these methods has advantages from an analytical point of view but each also gives rise to various conceptual and/or compilation problems.

24. Direct allocation of imports is appropriate for many analytical purposes. However, if substitution between imports and domestic production is known to occur, in order to allow for the probable effects of specified import replacement or substitution it would be necessary to adjust the imports matrix and to recalculate the industry-by-industry tables. In addition, the application of this method requires identification of the destination of each imported commodity. Although the proportion of imports in total supply (and therefore in total usage) for each commodity can be established, it may not be known for individual using sectors. Of course, it is possible to proceed if one assumes that each using sector draws on imports and local production in the average proportions established for the total supply of each commodity. In this publication, tables with direct allocation of competing imports have been prepared using this assumption. The assumption was applied to detailed working matrices (approximately 1,300 commodities and 109 industries) which were subsequently aggregated for publication.

25. Indirect allocation of imports is appropriate, in the sense that it will result in stable input-output coefficients, where the inputs to the domestic sector to which each imported commodity is primary are representative of the inputs required to produce the import domestically. Where this is not so, the method will give misleading results. For instance, if coffee (which is treated as a complementary import) were distributed with the *other agriculture* commodity (01.06), an increase in the demand for coffee would necessitate an increase in the output of the *other agriculture* industry (01.06). This, in turn, would require an increase in the inputs to that industry as specified in the published tables unless a specific adjustment is made to the tables. It is easy to compile tables using this method. The only problem which has to be overcome is matching each imported commodity with the local industry to which the commodity is primary, or would have been primary if it were produced locally.

26. The third method modifies the second to take account of complementary imports. To apply this method, it is necessary to distinguish between competing and complementary imports, so that the latter can be allocated directly to the using sectors. This distinction may appear to be obvious at first sight, but in practice it is difficult to apply. A competing import can be defined as one which is a good substitute for a locally produced commodity. However, in general, this cannot be determined objectively and so is largely a matter of judgement. Moreover, each competing import has to be matched with a locally produced commodity and this also presents difficulties because rarely is there a one-for-one correspondence between local and imported items.

27. Complementary imports could be defined as those for which no suitable substitute is produced locally, but determining what is a suitable substitute is largely a matter of judgement. Since complementary imports should

be allocated directly, it is necessary to identify their destination which may present some practical difficulties. However, the number of commodities involved is usually small and the nature or the description of these commodities frequently provides sufficient guide to their probable destination.

28. In principle, complementary imports are those commodities not produced in Australia (e.g. natural rubber) but the practice is somewhat different. All imports for which there is insufficient information to classify to a specific industry of origin, are treated as complementary imports in these tables. Other imports which, in principle, are complementary are not treated this way if they have a value of less than \$1 million in ABS import statistics. Appendix D provides a list of imports which have been treated as complementary (including the unclassifiable commodities).

Treatment of customs duty and excise tax

29. Customs duty has been allocated in conjunction with imports in all tables. This treatment implies that the landed value of imports (including duty) is considered to be conceptually comparable with the value of similar domestic products at basic values. However, this does not apply to customs duty on commodities for which an excise tax is levied on domestic production. These duties have been defined to be a component of commodity taxes (net). In tables with indirect allocation, competing imports c.i.f. and their duty are distributed together in rows 01.01 to 93.01, but each of these components is shown separately, in rows P6B, P7B, in the column of the industry to which the commodities are primary. In these tables customs duty on complementary imports is shown in row P7A, in the column of the using sector.

30. In tables with direct allocation, imports c.i.f. and the corresponding duty are shown separately for complementary and competing imports in the column of the using sector. Since all imports are allocated directly in these tables, such a distinction may appear to be superfluous. It has been maintained because, while the (direct) allocation of complementary imports is based on the analysis of the nature of each commodity and its destination, the allocation of competing imports is based on the assumption that users draw on supplies from local and overseas sources in the proportion ascertained in total for each commodity.

Valuation of transactions

31. Input-output tables record only those flows of goods and services which have been locally produced, imported or drawn from local stocks during the reference period. Therefore some transactions are outside the scope of the input-output tables and so are not recorded in them. The most important exclusions are financial transactions, such as loans, interest, purchases of securities, etc. Other transactions have to be modified before they can be included in the tables. For instance, flows of commodities are commonly reported as sales and purchases, but the input-output tables should record output and usage. Output will differ from sales, and input (or usage) will differ from

purchases by the amount of stock change (positive or negative) in both cases. Output is calculated as sales *plus* change in stocks of finished goods *plus* change in stocks of work in progress, and input is calculated as purchases *less* change in stocks of materials. Changes in stocks are recorded in a separate final demand column (Q6) in the row of the industry of origin. Entries in this column refer to changes in stocks of both locally produced and imported commodities, regardless of whether they are held by producers, dealers or intermediate users. Input-output tables do include some elements which are not market transactions, such as the rent of owner-occupied dwellings and home-produced food consumed on farms.

32. The flows in input-output tables can be valued in several ways. The choice depends partly on the intended use of the tables and partly on availability of data (including the assumptions that can reasonably be made where data are lacking). The valuation conventions most commonly used are basic values, producers' prices and purchasers' prices. *Basic value* is the 'ex-plant' value or net price received by the producer exclusive of indirect taxes less subsidies. *Producer's price* is the price received by the producer inclusive of indirect taxes less subsidies and exclusive of margins. *Purchaser's price* is the cost of the commodity to the purchaser. The difference between the cost of a commodity to the purchaser and the net price received by the producer is composed of margins such as transport and storage services, marine insurance, and wholesale and retail margins. Regardless of whether the producer or the purchaser initially pays for the margins, the concept of producers' prices excludes the margins and the concept of purchasers' prices includes them.

Margins

33. If the transactions are valued at producers' prices, the margins are recorded as inputs from the appropriate sector (e.g. transport, wholesale trade) to the intermediate users or final buyers, as the case may be. If the transactions are valued at purchasers' prices these elements are shown as inputs to the producing sector whose output, including all marketing costs, is then absorbed by users. However, where imports are allocated directly they cannot be said to originate in any local producing sector and the margins on these imports have to be shown as inputs to the using sector.

34. Whichever method is used, a complicated estimation process will be necessary before the transactions can be valued in one of these ways. First, input and output statistics from economic censuses are not available on the same valuation basis. Most output statistics are on an ex-plant or similar basis but input statistics are normally available at the price paid by the user. Second, margins apply only to those flows of commodities which have actually passed through the 'margin' industries. Any commodities delivered directly from producer to user, without intervention of 'margin' industries, are obviously unaffected by margins.

35. The incidence of margins can vary considerably between users, depending on the channels through which they obtain their supplies. For instance, most producers

would not buy their requirements through retailers while practically all households do so. If transactions are recorded at purchasers' prices, then the relevant margin elements of marketing costs are shown as inputs to the producing sector and thus become a function of its output. There is no reason to expect this function to be stable over time. Any change in the disposition of the output may affect the channels of distribution and, therefore, the level of inputs from the 'margin' industries, although the nature and the level of the output itself may remain unchanged. The valuation at producers' prices avoids this difficulty and results in more stable input coefficients.

Commodity taxes and subsidies

36. The treatment of commodity taxes in input-output tables creates special problems which can only be solved by the use of conventions. The concept of producers' price includes commodity taxes. If transactions are valued at producers' prices, commodity taxes are recorded as being paid by producers. However, commodity taxes do not accrue to producers, are not levied on all commodities, and can vary significantly between different uses and over time, for reasons which have nothing to do with production. For instance, sales tax may not be payable on exports or on government purchases of some commodities, but it may be quite heavy on the same commodities bought for personal consumption. Therefore, if commodity taxes were included in the value of commodities on which they are levied, the flows would not be valued uniformly and the subsequent manipulation of the tables could give quite erroneous results. This problem can be avoided by recording the commodity flows at the value at which they leave the producers before commodity taxes are charged and showing these taxes separately from the commodity flows where they arise. When this procedure is adopted, the flows are said to be at basic values and this is the basis of valuation adopted in most tables in this publication. In these tables all flows of commodities exclude both commodity taxes and indirect taxes. These taxes are shown in separate rows. Commodity taxes are shown as being paid by the users of the commodities on which the taxes are levied, while indirect taxes, n.e.c. are shown as being paid by the industry that incurred them. In tables at producers' prices and at purchasers' prices, commodity taxes are shown as paid by the producer of commodities subject to tax. As with margin elements, this treatment of commodity taxes results in lack of uniform valuation of commodity flows and in the distortion of input-output relationships.

37. Commodity specific subsidies are treated as negative commodity taxes and the amounts shown in row P3 represent the difference between the two. In tables at basic values, commodity taxes are recorded as paid by purchasers. If the purchasers also bought some commodities which attract a subsidy, the amount of subsidy is deducted from commodity taxes paid by them. For example, the dairy industry subsidy is included in column 21.02, row P3 as negative tax of the *milk products* industry (21.02). In a table at purchasers' prices, commodity taxes are shown as paid by producers of commodities subject to tax and subsidies are recorded as a negative tax on producers.

Reconciliation of flows

38. A summary reconciliation between the flows at basic values and at purchasers' prices is provided in Table 4, which shows the intermediate usage and final demand of each commodity group. In each set of four columns, the first column shows the usage at basic values for each category. Since competing imports are allocated indirectly in this table, the flows include both local products and competing imports and are therefore the same as in Table 2. The second and third columns show the commodity taxes less subsidies and the margin, respectively, associated with the figures in the first column. The sum of entries in the first three columns equals the usage at purchasers' prices. Detailed information about the type of margin on each flow in Table 2 is provided in detailed margins matrices available on floppy disks. Details concerning the availability of these are shown in Appendix F.

Margin and non-margin commodities

39. As noted earlier, if the flows were at purchasers' prices, the elements of margin would be recorded as inputs to the producing sector. However, the supply of commodity groups containing margin commodities consists of two parts: that which involves the movement of goods and that which represents other (non-margin) commodities. Only the first of these parts (e.g. freight of goods by rail or road) is treated as margin and allocated differently depending on whether the flows are at basic values or at purchasers' prices. The second part (e.g. railway fares) is treated as non-margin and is always shown as paid by purchasers. The components of the commodity groups contributing margin are provided in Table 23.

40. When reading Table 4 the following should be kept in mind:

- (a) The entries in the rows containing margin commodities include the supply of the margin in the first column. This margin is shown separately in the third column. Only the non-margin supply is shown in the fourth column.
- (b) In some rows there are no margin entries. This happens not only with services but also with some goods producing industries whose output either goes from producer to user without the intervention of margin industries (e.g. construction) or has been defined so as to include distribution (e.g. electricity).
- (c) The figures at basic values in the *sales by final buyers* row (P5) are net figures (i.e. they represent the difference between purchases and sales by a particular sector) although margin figures in this row relate to purchases. Consequently, some margin entries in the row may look out of proportion to corresponding figures at basic values.

Assumptions made in compiling tables

41. The results of users' analyses will be correct to the extent to which input-output coefficients are stable, which in turn depends on the extent to which the main assumptions underlying the input-output estimates have been satisfied. One of these, the *homogeneity assumption*, postulates that:

- (a) each sector produces a single output (i.e. all the products of the sector are either perfect substitutes for one another or are produced in fixed proportions);
- (b) each sector has a single input structure (i.e. one which does not vary in response to changes in product mix);
- (c) there is no substitution between the products of different sectors.

The other, called the *proportionality assumption*, postulates that the change in output of an industry will lead to proportional changes in the quantities of its intermediate and primary inputs (i.e. for any output, each of these inputs will be a fixed proportion of the total). Even though these assumptions may be realistic for the reference year, they became progressively less so for later years. The homogeneity assumption may be weakened by changes in product mix (and consequent changes in inputs), introduction of new products and/or materials, and substitution of imports for local production or vice versa. The proportionality assumption may be invalidated by economies of scale, technological change or substitution of factors (e.g. more capital, less labour).

42. The analyst may be in a position to allow for some of these changes. Estimates of input changes due to changed technology may be obtainable from technical experts or other sources and adjustments can be made for import substitution. These adjustments should be made to a table of direct requirements or a transactions table but not to a table showing total requirements. If desired, the adjusted table can then be used to derive new total requirements coefficients.

43. The input-output tables in this publication represent an open input-output system because the final demand sectors are *exogenous*, that is, determined by factors outside the system. In a closed system, all sectors are defined as interdependent which means, for example, that household consumption is treated like an industry and its inputs (i.e. the requirements of consumers) are part of the solution. The system in this publication is static because it takes capital accumulation as exogenously determined. Dynamic systems introduce explicit periods of time into the relationship between capital and output.

Derived tables

44. The basic matrices and the industry-by-industry tables are essentially an accounting record of the flows in the economy in the reference year. Using simplifying assumptions the input-output estimates can serve many

analytical purposes. For instance, it is possible to estimate the levels of output of the production sectors required by a given final demand. The effect on other industries of an additional final output of \$100 million of the *motor vehicles and parts and transport equipment n.e.c.* industry (32.01) or of a 25 per cent change in exports of minerals can be calculated by assuming that average and marginal utilisation rates are the same. An impact analysis of this kind may be concerned with one, several or all sectors of the economy and can be carried out with the aid of the requirements tables described below. Because relative prices are continually changing and do change substantially from one year to the next (e.g. internationally-traded basic commodities), it is useful to regard input-output tables as representing underlying quantities and technological relationships rather than values and value relationships. Even factor payments (wages, salaries and supplements and gross operating surplus) can be viewed as representing underlying quantities, namely quantities of employee services and of entrepreneurial and capital services. Unless the analyst makes adjustments for price changes, all proportions and values are in terms of the relative and absolute prices of the reference year.

Impact analysis

45. An impact analysis under an open static system is usually carried out with the aid of a set of derived tables. These tables can be derived from any of the flow tables, the choice depending on the nature of the proposed analysis. The first derived table is a matrix of direct requirements coefficients. The second matrix, deduced from the first, is a table of total (i.e. direct and indirect) requirements coefficients.

46. By further manipulation of the derived tables, it is possible to produce special tables which go beyond impact studies and bring out other relationships. Two examples only of such special tables (Tables 17 and 18) are included in this publication to indicate some of the further possibilities of input-output analysis.

Direct requirements coefficients

47. A very simple application of the input-output table is calculating inputs as a percentage of the output of an industry and using these percentages for estimating the input requirements for any given output of that industry. In all the tables included in this publication (including tables with indirect allocation of imports), 100 per cent always represents total Australian production which is shown in row T2 in tables with indirect and direct allocation of imports. For example, for the *transport equipment* industry (16), Australian production is found in column 16, row T2 in Tables 11 and 14.

48. Direct requirements coefficients have different meanings depending on the treatment of imports in the flow table from which they are derived. If the flow table were characterised by a *direct allocation of competing imports* the coefficients in Quadrant 1 would only refer to the requirements for local production. For example, Table 12 shows that \$100 of output of the *transport equipment*

industry (16) involves a direct requirement of Australian production from the *basic metals and products* industry (14) of \$7.70 (column 16, row 14). The requirement of transport equipment for imports is \$16.96 (rows P6A plus P6B). A detailed classification of imports by commodity is provided in the imports matrix (Table 3). Therefore, in using the direct requirements coefficients it would be necessary to assume unchanged usage of imports or, alternatively, to recalculate the coefficients using revised import usage characteristics. The usage of imports is also shown in Table 3.

49. If the flow table were characterised by an *indirect allocation of competing imports*, the coefficients in Quadrant 1 would include the usage of both imported and locally produced commodities. For example, Table 15 shows that \$100 of output of the *transport equipment* industry (16) involves a direct requirement of Australian production plus imports from the *basic metals and products* industry (14) of \$8.93 (column 16, row 14). Therefore, if the usage of a commodity by an industry remains unchanged, substitution can take place between imports and domestic production without affecting the size of the coefficients.

50. The coefficients for wages, salaries and supplements, gross operating surplus, commodity taxes (net), indirect taxes n.e.c. (net) and sales by final buyers are the same regardless of whether they are derived from the tables with indirect or direct allocation of competing imports. However, the coefficients for imports and customs duties differ between these two types of tables. In the tables with an indirect allocation of competing imports, the entries in Quadrant 3 (the primary inputs quadrant) relate only to complementary imports; competing imports are included in Quadrant 1 since this shows the requirements of any given industry for the output of other industries and competing imports primary to those industries. In tables with a direct allocation of competing imports, the import entries relate to all imports used by the industry in the column.

Total requirements coefficients

51. The chain of calculations of output requirements can be continued beyond the direct requirements of an industry. For example, in order to produce output from the chemicals industry, inputs are required directly from the mining industry. But to supply this direct requirement, the mining industry itself requires inputs from the chemicals industry. To produce this indirect requirement of the mining industry, the chemicals industry needs, in turn, additional output from the mining industry, and so on in a convergent infinite series. This example has been confined to two industries directly dependent on each other but indirect requirements can arise even in the absence of direct dependence. For example, the mining industry may not directly require any inputs from agriculture but it requires inputs from chemicals which cannot be satisfied without input from agriculture. Therefore, there is an indirect requirement by mining for agricultural input.

52. The requirements can be traced, step by step, throughout the industrial structure, until the increments of output required indirectly from each industry become insignificant (which occurs after a few rounds). If this operation is carried out for all industries and the direct and indirect requirements are added together, a matrix of total requirements coefficients is obtained. However, if the number of industries is large the iterative method is too cumbersome and so the total requirements are calculated on a computer by the method known as matrix inversion. This is why the matrix of total requirements is frequently described as the inverse matrix and its coefficients as inverse coefficients. In this publication, they are referred to as *total requirements coefficients* and they are shown in Tables 7, 10, 13 and 16.

53. In these tables a coefficient at the intersection of row i (a typical row) and column j (a typical column) represent the output of industry i required directly and indirectly to produce \$100 of output absorbed by final demand (i.e. final output) of industry j . In using these coefficients one should bear in mind the assumptions about homogeneity and proportionality which are their foundation.

54. It should be noted that coefficients will differ according to the way imports have been allocated in the flow table on which the coefficients are based. If the flow table were characterised by a direct allocation of competing imports, the total requirements coefficients in Quadrant 1 would refer only to the requirements for local production. For example, Table 13 shows that \$100 of final output of the *transport equipment* industry (16) involves a direct and indirect (or total) requirement of Australian production from the *basic metals and products* industry (14) of \$12.82 (column 16, row 14). Therefore, in using the coefficients, it would be necessary to assume unchanged usage of imports or, alternatively, regulate the coefficients using revised import usage characteristics. The usage of imports is shown in the imports matrix (Table 3).

55. If the flow table is characterised by an indirect allocation of competing imports, the total requirements coefficients of Quadrant 1 include the usage of both imported and locally produced commodities. For example, Table 16 shows that \$100 of final output of the *transport equipment* industry (16) involves a direct and indirect (or total) requirement of Australian production and imports from the *basic metals and products* industry (14) of \$18.91 (column 16, row 14). Therefore, providing the usage of a commodity by a particular industry remains unchanged, substitution can take place between imports and domestic production without affecting the size of the coefficient. In using these total requirements coefficients, a separate assessment of the proportion of these requirements which is likely to be satisfied by imports would need to be made, unless it can be assumed that the requirements to meet a specified level of final demand can be satisfied from domestic production.

56. All coefficients in the requirements matrices relate to flows from industry to industry. Consequently, the answers obtained by applying these coefficients will be in

terms of the output of industries and not commodities primary to these industries.

57. All tables of total requirements coefficients characteristically have a diagonal entry in excess of 100. These small excesses over 100 shown in all diagonal entries are due to indirect requirements affecting each industry through other industries. This means that to meet \$100 of final demand for the output of a particular industry, the industry itself has to produce that \$100 (for final demand) plus any direct or indirect requirements for its output resulting from its requiring inputs from itself or other industries.

58. Impact calculations in an open input-output system require independent specification of final demand for the output of each sector in the table. If final demand is specified at purchasers' prices while the answer is sought in basic values, the reduction of the former to the latter can be carried out with the aid of Table 4.

Specially derived tables

59. Instead of being expressed as total output, the requirements can be expressed as primary input content. This amounts to looking at the other side of the fundamental national accounting identity which says that gross national expenditure plus exports of goods and services is equal to gross domestic product plus imports of goods and services. In other words, the final output of any industry is equal to the rewards paid to factors of production (wages, salaries and supplements; and gross operating surplus) and other primary inputs (indirect taxes less subsidies, imports and sales by final buyers) in all industries contributing directly and indirectly to this final output.

60. Each entry in the total requirements matrix represents the total output required from the industry in the row by the industry in the column for the purpose of producing \$100 of output absorbed by final demand. But each of these entries can also be thought of as the sum of its inputs and hence can be dissected into these individual components. The proportions obtained from the column of the supplying industry in the matrix of direct coefficients are used. These calculations are based on tables with direct allocation of all imports. According to the proportionality assumption (see paragraph 41), the amount of each kind of input used by an industry represents a fixed proportion of that industry's output.

61. Table 17 is derived as described above from Tables 6 and 7. In the columns it shows the amount of each primary input contributed by all relevant industries to \$100 of final output of the industry in the row. The accounting identity mentioned in paragraph 59 means that the sum of entries in each row must equal \$100. The last row in the table can be interpreted as the composition of final demand in terms of primary inputs.

62. The table shows the amount of each primary input in \$100 worth of each industry's output entering final demand. As might be expected, the primary input composition of final output varies between industries.

Thus, it can be seen that wages, salaries and supplements incorporated in final output range from 9.5 per cent in the case of *ownership of dwellings* (61.06) to 82.7 per cent in the case of *education, museum and library services* (72.01), while the ultimate complementary imports c.i.f. content of final output varies from 0.1 per cent in the case of *education, library and museum services* (82.01) to 4.2 per cent in the case of *defence* (72.01).

63. The calculations necessary to ascertain the amount of any primary input in \$100 of final output of any industry as shown in Table 17 may be illustrated by taking as an example the *motor vehicles and parts and transport equipment n.e.c.* industry (32.01) and by referring to Tables 6 and 7 (see the microfiche). From Table 7, it can be seen that to produce \$100 of final output, industry 32.01 needs, directly and indirectly, \$9.33 of output from the *basic iron and steel* industry (29.01). The primary input content of this output will be found in column 29.01 of the direct coefficients matrix (Table 6). Thus, wages, salaries and supplements represent 15.5 per cent, gross operating surplus 14.9 per cent, commodity taxes (net) 0.4 per cent, indirect taxes n.e.c. (net) 0.6 per cent, sales by final buyers 1.5 per cent, complementary and competing imports 0.2 per cent and 8.5 per cent respectively, and duty on these imports 0 per cent and 0.3 per cent respectively. If we were to multiply each of these percentages by the input from industry 29.01 to industry 32.01, we should obtain the content of each primary input of industry 29.01 in \$100 of final output of industry 32.01. If similar calculations were carried out for each entry in column 32.01 of Table 7 and summed, it would be found that \$100 of final output of industry 32.01 incorporated the following amounts of each primary input contributed directly and indirectly by all industries on which industry 32.01 relied for its supplies:

	\$
Wages, salaries and supplements	34.25
Gross operating surplus	34.31
Commodity taxes (net)	1.81
Indirect taxes n.e.c. (net)	1.81
Sales by final buyers	0.44
Complementary imports	0.39
Duty on complementary imports	0.00
Competing imports	25.10
Duty on competing imports	1.89
Total	100.00

Primary input content of final demand categories

64. For some purposes, it may be necessary to calculate the primary input content of each final demand category (shown in Table 18). In rows 01.01 to 93.01 there are two columns under each final demand heading. These show, for each industry, the wages, salaries and supplements and the gross operating surplus ultimately absorbed by that final demand category. Rows P3 to P7B show the other primary inputs which both directly and indirectly are included in that final demand. In this table these other primary inputs and the total of all primary inputs are shown in the lower part of the column for gross operating surplus. The entries in the table are in value terms and the

sum of all entries under each final demand category is equal to the total for that final demand category as shown in the various transactions tables. The figures in the last column of Table 18 represent value added at factor cost (ie, wages, salaries and supplements *plus* gross operating surplus) for each industry, and the total value of each of the other primary inputs.

65. The table indicates the extent to which each primary input depends, directly and indirectly, on each category of final demand. For instance, it can be deduced from the table that wages, salaries and supplements accounted for 35.1 per cent of final consumption expenditure of households, 66.8 per cent of government final consumption expenditure and 31.0 per cent of exports, while commodity taxes (net) accounted for 7.7 per cent of final consumption expenditure of households, 1.3 per cent of government final consumption expenditure and 3.6 per cent of exports. In addition, the total effect of a category of final demand on each industry may be considered rather than the direct effect which could be deduced from a transactions table. For example, according to Table 8 there are only very small exports of the output of the *electricity* industry (36.01). These are electricity purchases by diplomatic posts in Australia and electricity supplied in Australian ports to ships operated by non-resident transport enterprises. Table 18 shows that a much larger percentage of the value added by the *electricity* industry is indirectly incorporated in the exported output of other industries.

Sources and methods

Classification of industries and commodities

66. The industrial classification used for the 1989-90 input-output tables is based on the 1983 edition of the *Australian Standard Industrial Classification* (ASIC), but, in some respects, departs from the usual application of that classification. ASIC is mostly applied to establishment units and this is the starting point for most of the input-output industries. However, for input-output tables it is desirable that an industry corresponds as closely as possible to the production of commodities primary to that industry. This applies especially where establishments classified to an industry produce significant amounts of commodities primary to another industry which has quite a different pattern of inputs. In these cases, where practical, secondary or subsidiary production is treated as output of the industry to which production is primary; this process is called *redefinition of production*.

67. The following are the major redefinitions made. Trading activity of miners and manufacturers is redefined to wholesale or retail trade, and any significant manufacturing activity of wholesalers, is redefined to appropriate manufacturing industries. The input-output industries *mechanical repairs* (49.01) and *other repairs* (49.02) have no counterpart in ASIC. They are formed by redefinition of the repair activity undertaken by wholesalers and retailers. Significant capital work on own account, where not primary to the industry of the establishment undertaking the activity, is redefined to construction or an appropriate manufacturing industry.

The imputed component of the *ownership of dwellings* industry (61.06) is specified in the 1983 ASIC as being part of the *residential property operators* industry (ASIC class 6321). In addition, there are some areas of the economy - for example *construction* (41.01, 41.02) and *agriculture* (01.01 to 02.00) - where the nature of available data or other considerations may preclude a strict adherence to ASIC sectoring. In these areas, the input-output industries are formed by the redefinition of commodities from an ASIC sector.

68. Some of the input-output industries correspond to single ASIC classes but it is not practicable to have an input-output industry for each ASIC class. The aim is to provide both a balanced picture of the structure of the economy and comparability between the latest input-output tables and earlier ones. For details, see Appendix B. Details of the Australian Input-Output Commodity Classification (IOCC) and concordances between the items in the classification and data source items of production, imports and exports are provided in publication 5215.0.

Industry output

69. In general, the output of industries is defined as the production of goods and services for use as inputs into industries or into final demand. Own account transportation is not shown separately but rather is included indistinguishably with the rest of producer's output. The estimation procedures used for each industry and the main changes from previous tables are given below.

70. In *agriculture* (01.01 to 01.06), the value of output is the ex-farm or local value which is estimated by valuing quantities of the various products. (The data are obtained mainly from the annual Agricultural Census and the Agricultural Finance Survey.) The value of containers, such as bags and cases, is added where appropriate to the *local* value of output to bring the treatment of rural industries into line with that of manufacturing industries. In *services to agriculture* (02.00) the value of output is estimated by reference to measures of the usage by industries and in final demand of commodities primary to services to agriculture. The output of *forestry and logging* (03.00) includes the value of forest products, and government and private current expenditure on management of forest resources. The information comes partly from ABS collections and partly from the reports of public authorities. The output of *fishing, trapping and hunting* (04.00) is the *local* value of the *fish and game* obtained from ABS and ABARE collections.

71. In *mining* (11.01 to 14.00), *manufacturing* (21.01 to 34.05), *electricity* (36.01) and *gas* (36.02), the estimates of output are based on information obtained in ABS economic censuses.

72. The starting point for the estimates of output is the sum of the following items derived from data collected in the economic censuses:

- sales and transfers-out of goods produced on the premises *plus* change in stocks of finished goods and work in progress;
- margin on merchanted goods;
- capital work on own account;
- other specified operating income items.

The initial estimates for some industries have a product which is not satisfactory for input-output purposes and in these cases some secondary output and associated inputs are shifted to the industry to which the output is primary.

73. In particular, it is important not to mix processing activity with trading activity because trading activity is treated in a special way in input-output tables. Accordingly, the trading activity of mining, manufacturing and electricity establishments is redefined, partly to wholesale trade and partly to retail trade. In doing this, it is assumed that the mining and manufacturing industries as a whole generally traded the same goods in the same proportions as did the wholesale and retail trade industries. It is also assumed that the percentage margin earned on these goods by manufacturers is the same as that earned by wholesalers or retailers dealing mainly in similar goods. For the purpose of redefinition, it is also necessary to estimate the inputs into gross margin earned by manufacturers. These estimates are based on the input structure of wholesalers or retailers.

74. Apart from trading activity, it is necessary to examine other components of the output of the *mining, manufacturing and electricity and gas* industries. Capital work on own account is the subject of special investigations undertaken to determine whether or not the activity is typically primary to the industry reporting it. In those cases where capital work on own account is large, where the activity is primary to another industry and where it is possible to identify the relevant inputs then it is desirable to redefine the capital work on own account to the industry to which it is primary. In other cases, where the capital work on own account is not primary to the producing industry, it is treated as output secondary to that industry.

75. Information on a range of other specified operating income items is also collected on economic census forms. Investigations are undertaken for industries where revenue from manufacturing on commission is significant. Where commission work is carried out for a different non-manufacturing ASIC class, estimates are made of the value of the commodities produced and materials used and these are transferred to the industry to which the commodities are primary (usually the industry of the establishment carrying out the commission work). The commission is absorbed by inclusion in value of production. Where the commission work is carried out for establishments coded to a manufacturing ASIC class, the value of commodities produced is recorded in the output of the industry commissioning the work. It is assumed that the commissioning establishment does not further process

the goods. The commission is recorded as an intra-industry flow.

76. Rent and leasing revenue is collected on economic census forms, and investigations have been conducted into the components of this revenue. Where the value of rent and leasing revenue is large, it is redefined. In other cases, it is treated as secondary production of the industry receiving it. Payments for rent and leasing are treated as purchases of commodities by the industry making the payment.

77. For tables published for reference years prior to 1983-84, the major component of the output estimate for the *services to mining n.e.c.* industry (16.00), consisted of the revenue of establishments that provided services to the mining industries. The main service provided is drilling (on a contract or fee basis). For the tables in respect of reference year 1983-84 and subsequent years, the estimate of output includes the value of exploration activity undertaken on own account. This refers to the exploration undertaken by establishments as a service to their parent enterprises and for which these establishments receive no revenue. The output value attributed to this activity is the current cost of providing the service i.e. wages paid plus cost of goods and services used by these establishments. Services to mining such as assaying and geological surveying are excluded from this industry and are included in the *other business services* industry (61.05).

78. The estimates of the output and input for the *services to mining n.e.c.* industry (16.00) are derived using information from the Input-Output Supplementary Survey program in combination with information obtained from the ABS surveys of mineral and petroleum exploration.

79. The input value for the industry reflects production costs associated with the services mentioned above. The inclusion of the value of exploration activity undertaken on own account means that a positive gross operating surplus is recorded for the *services to mining n.e.c.* industry. This output value is shown as being used by the other mining industries; the estimate of gross operating surplus of those industries is reduced by a corresponding amount, and the net effect on the estimates of gross domestic product is, therefore, zero.

80. The output of the *residential building construction* industry (41.01) represents the value of work done on new dwellings and the value of repairs to dwellings. The output of *other construction* (41.02) comprises new construction other than on dwellings and all repairs to non-dwelling buildings and structures carried out by the construction industry. The estimates of the output of the *residential building construction* (41.01) and *other construction* (41.02) industries are based on information from a number of different sources, including ABS building statistics, surveys of construction and engineering construction, income tax data, public accounts, annual reports of public enterprises, other economic census and survey data (for own-account construction and sales of construction materials), the Household Expenditure

Survey (for expenditure on construction and construction materials), etc.

81. The output of *wholesale trade* (47.01) and *retail trade* (48.01) is defined as gross margin on goods traded (difference between sales and cost of sales *plus* commission receipts) *plus* non-margin receipts. The value of goods handled is not included in the output of wholesalers and retailers who are thus considered to sell only distribution services. Estimates for the output of the *wholesale trade* (47.01) and *retail trade* (48.01) industries are based on information from ABS economic censuses and surveys of these industries. Note also that some wholesale and retail activity is redefined from other industries such as manufacturing. However, wholesalers and retailers sometimes engage in activities other than distribution such as manufacturing, repairing and leasing. In order to keep the distribution output separate, these activities should be either redefined to an appropriate industry or should be shown separately as non-margin output. These non-trading activities are treated as follows:

- manufacturing activity of wholesalers is redefined to an appropriate manufacturing industry;
- repair activity of wholesalers and retailers is redefined to one of the industries *mechanical repairs* (49.01) or *other repairs* (49.02) as appropriate;
- rent and leasing revenue and service revenue, are treated as non-margin output of *wholesale trade* (47.01) or *retail trade* (48.01).

82. After the separation of non-trading activities, the gross margin on goods traded is estimated in total and by commodity. The margin on individual commodities is estimated by reference to the results of periodic ABS economic censuses and surveys of the wholesale trade and retail trade industries, to the results of supplementary investigations, and to the supply of commodities at basic values and usage at purchasers' prices.

83. In the *transport and storage* industries (51.01 to 57.01) the output is defined as revenue derived from the activity of carrying goods and passengers for hire and reward, the storage of goods, and the provision of other transport services. As with wholesale and retail trade, it is necessary to distinguish between the carriage of goods (freight) which forms part of the margin, and other services provided by transport industries which do not (e.g. furniture removal and passenger transport). Total rail, pipeline, air and water transport revenues are extracted from the reports of the enterprises concerned as far as possible. The estimate of output of the road transport industry is built up from information about items such as the supply of goods potentially carried, primary inputs, motor vehicle running costs, miscellaneous other costs, revenue for services provided, and data collected in ABS surveys such as the Survey of Motor Vehicle Usage, the Transport Industry Survey, a survey of registered business vehicles and an input-output supplementary survey on transport and storage. The estimates of transport margin by commodity are approximate because of the limited

information about the type of goods carried by each mode of transport.

84. The *communication* industry (59.01) in 1989-90 included Australia Post, Telecom, OTC and AUSSAT. Estimates of output are based on the published accounts of these bodies and unpublished information made available by the enterprises. The output of the industry consists of postal, telegraph, telephone and telex revenue; commission earned on agency services (such as conduct of savings bank agencies); technical services provided to national broadcasting and television stations; international communication services and telecommunications satellites; and the coastal radio services.

85. In the *finance, property and business services* industries (61.01 to 61.06), the definition of output of banks and similar financial enterprises (other than insurance companies) differs from that of other enterprises. The activities of these enterprises are financed to a large extent, or even predominantly, by the excess of the interest they receive over the interest they pay out. If they were treated similarly to trading enterprises (i.e., if their output were taken as equal to their explicit charges for services provided) it would not be sufficient to cover all their costs and to produce an operating surplus. Because of this characteristic of financial enterprises it is necessary to adopt a treatment different from that for non-financial enterprises. The convention adopted in Australian input-output tables from 1968-69 is that part of the interest received by financial enterprises is considered to be a service charge and, therefore, part of their output. This treatment is also followed in the national income, expenditure and product accounts where the imputed bank service charge is shown as negative operating surplus of a nominal industry. In the 1977-78 and subsequent input-output tables, the *imputed bank service charge* is included in the output of financial enterprises and disposed of to private final consumption expenditure and to individual industries. Because of the allocation of the imputed bank service charge to industries, it is taken into account in calculating the gross operating surplus for those sectors for which a net operating surplus is recognised and in calculating output for those sectors for which the gross operating surplus is defined to be equal to their consumption of fixed capital, in the case of general government, or zero, in the case of private non-profit organisations. In addition to the imputed bank service charge, the output of financial enterprises includes explicit charges made to customers as well as rent and leasing revenue.

86. The output of financial enterprises covered in the *insurance and services to insurance* industry (61.04) is also defined by a convention. The output of life insurance companies and superannuation and pension funds is defined as equal to the sum of administrative costs (i.e. wages, salaries and supplements; intermediate inputs; and indirect taxes n.e.c. (net)) and gross operating surplus. For other insurance enterprises, the output is defined as the difference between premiums received and claims paid. However adjustments are sometimes necessary. For example, for 1977-78 estimated output obtained by the

strict application of this definition was negative at the IOCC item level. The value of output was re-estimated by reference to the value of premiums and claims in adjacent periods so that a more realistic measure of output was obtained. The output of insurance brokers and other enterprises servicing the insurance industry is defined as the value of revenue received.

87. Information on the output of banks, non-bank financial institutions, insurance companies and superannuation funds is available from ABS collections, the Insurance and Superannuation Commissioner and the Reserve Bank. There is very little information for other enterprises in the *finance, property and business services* industries (61.00 to 61.06), and the output estimates are largely built up from the input side by adding together estimates of primary inputs and estimates of the usage of commodities primary to these industries. The scope of the ABS economic censuses has been expanded to include enterprises in the *business services n.e.c.* industry (61.05). Estimates of the output and input for this industry are derived using information from the Input-Output Supplementary Survey program in combination with information obtained from the ABS Service Industries Survey. For those activities primary to the industry not covered by the survey, estimates of output and input are derived from taxation statistics. The output of the *ownership of dwellings* industry (61.06) is gross rent of dwellings (actual rent paid in the case of tenanted dwellings and an imputed rent for owner-occupied dwellings).

88. The output of the *public administration* (71.01) and *defence* (72.01) industries is the production of goods and services by general government units coded to these industries. It represents the relevant current final expenditures of general government plus revenue received from the sales of goods and services. The output is conventionally valued as the sum of intermediate inputs (including the imputed bank service charge); wages, salaries and supplements; general government consumption of fixed capital; and indirect taxes. Ideally, the estimates would be on an accruals basis for consistency with estimates for other industries but the data required for this purpose are not available. (Most estimates based on public accounts are on a cash basis rather than an accruals basis.)

89. The output of the *health* (81.01); *education, museum and library services* (82.01); and *welfare and religious institutions and other community services* (83.01) industries consists of three components. The first of these is production of goods and services by general government units, which represents the sum of intermediate inputs; wages, salaries and supplements; and indirect taxes. (By convention, general government gross operating surplus equals consumption of fixed capital.) The second is production by trading enterprises, such as doctors in private practice and private garbage disposal contractors, which represents revenue from services provided. The estimates are derived using either data on inputs (e.g. wages, salaries and supplements) or business income from *Taxation Statistics* (Australian Taxation

Office). The last is production by the producers of private non-profit services to households, such as schools and churches, which is measured as the sum of intermediate inputs; wages, salaries and supplements and net indirect taxes. By convention, there is no operating surplus. The estimates are based on public accounts and a Survey of Community and Personal Services Industries, which was undertaken by the Input-Output Section in 1981-82.

90. The remaining industries, *entertainment and recreational services* (91.01) to *personal services* (93.01), cover a range of services rendered to persons and, to a lesser extent, to business. For the *entertainment and recreational services* industry (91.01), estimates are made using information from economic censuses where this is available (e.g. for motion picture theatres). Reasonable data are available from public accounts and published reports for public broadcasting and television stations. Total revenues are available for commercial broadcasting and television from the report of the Australian Broadcasting Control Board. For the remainder of this industry, the output estimates are built up from primary inputs, estimates of other costs and demand for the services provided.

91. In the *restaurants, hotels and clubs* industry (92.01), restaurants, cafes, licensed hotels, and licensed clubs are covered by the economic censuses and a considerable amount of data from these collections is available on the output of this part of the industry. However, some adjustments are made for input-output purposes. First, the output of the industry includes a margin on sales of goods (e.g. beverages and cigarettes) that is treated in the same way as retail margin. Second, part of the revenue from meals is excluded. The cost of food used is treated as a flow from the industry where it is produced to private final consumption expenditure or to intermediate inputs. The difference between takings from meals served in cafes, hotels, etc. and the cost of food used is treated as *meal preparation and presentation*, a service activity of this industry that forms part of its output. However, this part of output is not treated as a margin and is always allocated directly to the purchaser.

92. For the *personal services* industry (93.01), the economic censuses provide information about the output of men's and women's hairdressers, and laundry and dry cleaning establishments. For the remainder of the industry, output is estimated from the input side and from measures of the level of demand for the services provided.

Primary inputs

93. In general, primary inputs are conceptually and definitionally the same as the corresponding items in the national income, expenditure and product accounts and often the same estimates are used. However, imports in the input-output tables are shown c.i.f. rather than on the f.o.b. basis shown in national income, expenditure and product (and balance of payments) accounts estimates. The concepts and definitions for *wages, salaries and supplements* and *gross operating surplus* are the same but different data sources are used. Input-output estimates are based, wherever possible, on data obtained from the

integrated economic censuses or surveys rather than on the sources used for the national income, expenditure and product estimates.

94. Integrated economic census or survey data on wages, salaries and supplements are substantially complete for the industries covered, but several adjustments are made as a result of investigations into *other expenses* of industries. In some cases elements of wages and salaries (such as directors' fees and long service leave) are included under the economic census or survey item *other expenses* rather than under *wages and salaries*. For industries not covered in the economic censuses, the wages, salaries and supplements estimates are based on the sources used in national income, expenditure and product estimates.

95. Gross operating surplus of industries included in the integrated economic censuses or surveys is the residual obtained by subtracting from the value of output all intermediate inputs; indirect taxes; the stock valuation adjustment; and wages, salaries and supplements. In the light of investigations into other expenses of industries, adjustments are made to the census or survey figures.

96. Also, the allocation of the imputed bank service charge to industries reduces the value of the gross operating surplus of each industry by the amount of the service charge allocated to that industry. The gross operating surplus of the producers of government services is defined to be equal to general government consumption of fixed capital. This is the value, at current replacement cost, of the reproducible fixed assets used up during a period of account as a result of normal wear and tear, foreseen obsolescence and the normal rate of accidental damage. Unforeseen obsolescence, major catastrophes and the depletion of natural resources are not taken into account. For producers of government services, the value of their output is increased by the imputed bank service charge allocated to the relevant industries and the value of their gross operating surplus is not affected.

97. For the estimation of customs duties, reliable information is available from foreign trade statistics for net duties, both in total and by commodity. Reliable information is also available for the total value of commodity taxes (net). Commodity taxes are sometimes levied (or subsidies paid) on commodities or groupings of commodities which can be readily distinguished for statistical purposes (e.g. excise on beer, sales tax on motor vehicles etc.) and there is no allocation problem. In other cases, it is difficult to relate available commodity statistics to the description of commodities subject to various rates of tax and the allocation of the taxes to commodities and using sectors is approximate. The range of commodities covers services as well as goods.

98. Accurate figures for total indirect taxes n.e.c. (net) are available but there is little information on the distribution by industry. Fringe benefits tax and payroll tax are separately reported in the integrated economic censuses and surveys. For industries not covered by economic censuses or surveys, this information is not available. Payroll tax is allocated to industries in

proportion to wages and salaries. Motor vehicle taxes are first apportioned between persons and businesses, using Public Authority Finance information, and the business part is allocated to industries in proportion to motor vehicle running expenses. Other indirect taxes in this group are allocated to industries on various bases. Sometimes the nature of the tax determines the allocation e.g. road maintenance tax is allocated entirely to the *road transport industry* (51.01) and rates on residential property are allocated to the *ownership of dwellings* industry (61.06). In some other cases, information on indirect taxes is obtained in the course of investigating industry inputs.

Imports

99. Imports represent the value of goods and services purchased from foreign residents. Imports of goods are based on foreign trade statistics but with balance of payments scope, coverage and timing adjustments and an adjustment to exclude the value of exchange. For details of balance of payments adjustments to foreign trade statistics, see *Balance of Payments, Australia: Concepts, Sources and Methods* (5331.0). Imports of services are also based on balance of payments sources.

100. The definition of the value of imports c.i.f. has been revised to accord with SNA recommendations. It now includes freight on imports provided by Australian carriers which is offset by an export of a freight transport service so as not to affect the balance on goods and services.

Sales by final buyers

101. Sales by final buyers does not appear as a separate item in the national income, expenditure and product accounts. Gross fixed capital expenditure and final consumption expenditure include purchases of second-hand goods from other sectors net of sales by final buyers to other sectors. In input-output tables, this item is necessary to record the sales of capital assets (and used consumer goods) for scrap and the use of that scrap as a raw material in production. It is also used to record net sales of used motor vehicles; e.g. by business and government to households. At basic values the item has a zero total, sales being recorded as negative entries in final demand columns with balancing positive entries in the columns of the purchasing sectors. By definition, any part of margins in these transactions is output and is recorded as paid by purchasers. Imports are recorded as negative exports; duty on these imports is reported in the aggregate *commodity taxes (net)*. Scrap produced directly in the production process is treated as intermediate output and is not included in this item.

Intermediate inputs

102. Intermediate inputs into an industry consist of goods and services used in the process of production. A detailed discussion of the estimation of intermediate inputs using the Australian input-output methodology is provided in the ABS occasional paper *The RAS Method for Compiling Input-Output Tables: ABS Experience*.

103. Under the Australian input-output methodology, in any particular year some flows will be estimated by reference to basic data sources and included in the intermediate usage matrix as modifications. Other flows will be estimated using the RAS procedure.

104. Selected data from the 1987-88 Construction supplementary survey and the 1989-90 Mining and Manufacturing supplementary surveys of containers, packaging and materials used are the basis of extensive modifications to the input structure of the construction, mining and manufacturing industries. The input structure of the Defence industry has been substantially derived from data in the 1989-90 Defence annual report and ABS Public Finance data. There are also modifications to electricity and other fuels commodities as intermediate input to the mining, manufacturing, electricity and gas industries based on ABS census data. Overall, more than 40 per cent of the intermediate inputs (other than the imputed bank service charge) to all industries are derived from basic data.

105. The imputed bank service charge is allocated directly to using industries in a two-stage process. First, the charge is allocated to the institutional sectors *general government* and *financial institutions*, the *corporate trading enterprises* and *households* sectors combined, and to the industry *ownership of dwellings* (61.06) using the proportion of the total interest paid by those sectors to financial enterprises. No imputed bank service charge is allocated to the overseas sector. Second, the imputed bank service charge is allocated to the producing units of financial enterprises in proportion to interest paid to other financial enterprises. The remainder of the imputed bank service charge is allocated to the producing units of each sector according to the Australian production of the producing units.

106. Rows relating to the margin item *commodity taxes (net)* and to the following margin commodities: wholesale trade (47.01, part); retail trade (48.01, part); road transport (51.01, part); railway transport (52.01, part); pipeline transport (52.01, part); water transport (53.01, part; 5701, part); air transport (54.01, part); port handling (57.01, part); marine insurance (61.04, part); and restaurants, hotels and clubs (92.01, part) are wholly modified by *margin estimates* derived in the compilation of the nine margin matrices. The column totals of the margin matrices, which show the total usage of each margin by each industry, are then incorporated as values in the nine margins rows.

Final demand

107. The final demand categories in input-output tables are conceptually the same as in the national income, expenditure and product accounts but in practice there are some differences between the series. A description of their content and the differences between the two series is provided in Appendix E. Also each of these categories is classified by the industry of origin, whereas final demand is not disaggregated in this way in the national income, expenditure and product accounts.

108. Private final consumption expenditure is current expenditure (including household expenditure on motor vehicles and durables) by persons, and the output of goods and services by producers of private non-profit goods and services to households. Estimates of private final consumption expenditure are based largely on retail sales, supply of consumer goods, outputs of services, information about the revenues of public enterprises and general government, and estimates of the actual and imputed rent of dwellings. Estimates by industry of origin are based partly on the commodity dissection of retail sales provided by retail censuses and partly on data about the supply of consumer goods. Household expenditure survey results are used mainly to validate estimates of private final consumption expenditure provided by ABS economic censuses and surveys, especially for commodities produced by industries other than agriculture, mining and manufacturing.

109. Government final consumption expenditure is mainly the output of producers of general government goods and services less revenue from any sales, or charges in respect of that output. The classification of government final consumption expenditure by commodity differs from a classification by purpose in that, for example, departmental administration is classified to public administration and not to the activity administered (e.g. education). Estimates are based on public accounts.

110. Private gross fixed capital expenditure includes outlays on, additions to and replacement of fixed assets of all kinds by private enterprises. Purchase of dwellings by persons and all capital expenditure by private non-profit organisations serving households are included. Expenditure on major repairs which significantly extend the life of assets is included. Estimates of private gross fixed capital expenditure are based on a variety of sources including building statistics, a regular ABS survey of private capital expenditure and *Taxation Statistics*. To some extent both the total estimates for this category and the commodity estimates depend on the output of goods and services not absorbed by other final demand categories or intermediate usage. *Indirect taxes n.e.c. (net)* applying to transactions in land and fixed capital are included in private gross fixed capital expenditure. The estimates of the value of real estate transfer costs that are capitalised cover:

- stamp duties on all capital transfers;
- the cost of legal services, real estate services and surveying services associated with the purchase of dwellings;
- costs associated with transfers of agricultural or pastoral properties, and other non-dwelling real estate;
- conveyancing costs associated with the sale, as well as purchase, of real estate; and
- government charges.

111. Public gross fixed capital expenditure includes all outlays on additions to and replacement of fixed assets by public enterprises and by general government. However, all defence expenditure is treated as current and included in government final consumption expenditure. Estimates of gross fixed capital expenditure of public enterprises and general government are based on the accounts of public authorities and additional information supplied by these bodies. The classification of gross fixed capital expenditure of public enterprises and general government relies on information on the nature of the assets purchased and goods and services produced.

112. As in the national income and expenditure estimates, increase in stocks is calculated by deducting a stock valuation adjustment from the increase in book value of stocks. The major stock-owning industries are covered by the economic censuses and surveys, and information for other industries is available from *Taxation Statistics*, the accounts of public authorities and a regular ABS survey of private stock holdings. However, these sources do not provide a sufficient dissection of stocks by commodity. The allocation of the increase in book value of stocks to industry of origin is made by inference (but not by automatic apportionment) from the categories of goods sold by wholesalers and retailers and the finished goods of producers, and from the categories of material inputs. Estimating the stock valuation adjustment by commodity group requires similar inferences about the level of stocks, assumptions about valuation practices, and reliance on partial information about commodity prices.

Exports

113. Statistics relating to exports are obtained from the foreign trade and balance of payments collections. The category includes re-exports for which the corresponding import is included in the row *competing imports*. It also includes, as a negative entry, any imports of goods classified to sales by final buyers. The commodity detail provided in foreign trade and balance of payments statistics is used to allocate exports to input-output commodities. Exports of services include the value of freight supplied by Australian resident carriers on imports.

Employment

114. For some purposes, it may be necessary to examine the impact on employment by industry of changes in final demand. For this reason employment classified by Input-Output industry is presented in Table 22. Employment is measured on a full-time equivalent basis, that is, the full-time equivalent of part-time employment is added to full-time employment. For these estimates the full-time equivalent of part-time employment is assumed to be 50 per cent of the part-time employment. Employment estimates have been derived from two ABS sources, the Labour Force Survey and the Population Census. The Labour Force Survey estimates are the average of data for the middle month of each of the four quarters of 1989-90. Employment estimates derived from the Labour Force Survey are used to calculate employment multipliers which are published in *Australian National Accounts Input-Output Multipliers* (5237.0).

Employment estimates derived from the Population Census are also provided in order to meet the special needs of compilers of regional input-output tables. The differences between the estimates of employment derived from these two sources are explained in Census Working Paper 94/1, 1991 Census Data Quality: Labour Force Status, available on request. It should be noted that both sets of industry estimates have been adjusted to take account of the industry redefinitions for Construction and Repairs (see paragraphs 80 and 81) and to take account of the differences between the Input-Output and ASIC industry classifications for Agriculture (see Appendix B).

Relationship between input-output and other national accounting estimates

115. There are differences between primary input and final demand estimates included in this publication and the corresponding estimates for 1989-90 in *Australian National Accounts, National Income and Expenditure, 1991-92* (5204.0), although the concepts, but not the classifications, are the same. Work is proceeding on reducing the extent of such differences both in the context of the development of the system of input-output tables and as estimation methodologies for the national income, expenditure and product estimates are reviewed.

116. For 1989-90, the estimate of gross domestic product (GDP) implied by the primary inputs in the input-output tables is about 1.5 per cent higher than the estimate shown in *Australian National Accounts, National Income and Expenditure* (5204.0). The estimate of gross domestic product implied by final demand in the input-output tables is about 0.1 per cent lower than the estimate (excluding the statistical discrepancy) shown in 5204.0. Although a complete analysis and balancing of commodity flows results in internal consistency of input-output estimates of primary inputs (income) and final demand (expenditure), it does not necessarily make them more accurate or reliable than the estimates in 5204.0. The estimates can only be as good as the basic data and methodology used in their preparation and the basic data used for 1989-90 leave some gaps and have some deficiencies.

117. The differences which have been referred to do not imply anything about the relative precision of the input-output and national income, expenditure and product estimates, nor do they necessarily suggest deficiencies which would seriously affect most analytical uses of the tables included in this publication.

5401 Air transport	318	8,755	9,073
5701 Services to transport	485	6,763	7,248
6104 Insurance and services to insurance	80	6,977	7,057
9201 Restaurants, hotels and clubs	3,826	9,774	13,600
Total	87,227	43,629	130,856

APPENDIX A

ILLUSTRATION OF RAS METHOD

The following illustration is quoted from the publication *Input-Output Tables and Analysis, Studies in Methods*, Series F, No. 4, Rev. 1, United Nations, New York 1973. For simplicity the flows included are hypothetical. Except for algebraic notation which remains unchanged, the descriptions used in this illustration have been amended to correspond with usage elsewhere in this publication.

(a) Input-output table for year 0

Supply	Industry			Intermediate usage	Final demand	Total supply
	A	B	C			
Commodity A	50	100		150	50	200
	30	50	20	100	200	300
	20	50	30	100	100	200
Intermediate usage			50	350	350	700
Primary inputs			100	150	350	
Total usage			200	300	700	

(b) Available data for year 1

Supply	Industry			Intermediate usage u^*	Final demand	Total supply
	A	B	C			
Commodity A				160	40	200
				150	250	400
				120	180	300
Intermediate usage v^*			80	430	470	900
Primary inputs			100	220	470	
Total usage q_1			200	300	900	

(c) Input-output coefficients for year 0, matrix A_0 . The coefficients are obtained by dividing the intermediate usage recorded in each cell by total usage.

	A	B	C
A	.250	.333	0
B	.150	.167	.100
C	.100	.167	.150

The objective of the following operations is to obtain flows that satisfy the constraints u^* and v^* . That is the operations will continue until $u_n \equiv u^*$ and $v_n \equiv v^*$, where n is the number of iterations required for the condition to be met.

(d) Year 0 coefficients applied to year 1 total usage, matrix $A_0 q_1$ and calculation of first row multipliers (vector r_1).

	A	B	C	u_1	u^*	$r_1 = u^* \div u_1$
A	50	133.3	0	183.3	160	.873
B	30	66.7	30	126.7	150	1.184
C	20	66.7	45	131.7	120	.911
v_1	100	266.7	75			
v^*	100	250	80			

- (e) Adjustment of matrix along rows and calculation of first required *column* multipliers (vector s_1).
 Multiply the matrix at (d) along its rows by r_1 and obtain:

	A	B	C	u^*
A	43.6	116.4	0	160
B	35.5	79.0	35.5	150
C	18.2	60.8	40.1	120
v_2	97.3	256.2	76.5	
v^*	100	250	80	
$s_1 = v^* \div v_2$	1.027	.976	1.046	

- (f) Adjustment down columns and calculation of second required row multipliers.
 Multiply the matrix at (e) down its columns by s_1 and obtain:

	A	B	C	u_1	u^*	$r_2 = u^* \div u_1$
A	44.8	113.6	0	158.4	160	1.010
B	36.5	77.1	37.1	150.7	150	.996
C	18.7	59.3	42.9	120.9	120	.992
$v = v^*$	100	250	80			

- (g) Adjustment successively to rows and columns continues until both $u \equiv u^*$ and $v \equiv v^*$ with the final matrix:

	A	B	C	Row multipliers
A	45.3	114.7	0	.884
B	36.2	76.6	37.2	1.177
C	18.5	58.7	42.8	.902
Column multipliers	1.025	.974	1.054	

The completed table for year 1

Usage Supply	Industry			Intermediate usage u^*	Final demand	Total supply
	A	B	C			
Commodity A	45.3	114.7	0	160	40	200
	36.2	76.6	37.2		250	400
	18.5	58.7	42.8		180	300
Intermediate usage v^*	100	250	80	430	470	900
Primary inputs	100	150	220	470		
Total usage q_i	200	400	300	900		

MODIFIED RAS METHOD

(a) Available data for year 1

In this illustration the input of B to A is exogenously determined in year 1. The table is otherwise the same as the table in step (b) in the above illustration of the simple RAS method.

Supply	Usage			Intermediate usage	Final demand	Total supply
	A	Industry	C			
Commodity A				160	40	200
	40			150	250	400
				120	180	300
Intermediate usage				430	470	900
Primary inputs				470		
Total usage				900		

(b) Year 0 coefficients applied to year 1 usage.

The known input of B into A is excluded from the matrix and from u^* and v^* before the adjustment process begins.

	A	B	C	u_1	u^*	$r_1 = u^* \div u_1$
A	50	133.3	0	183.3	160	.873
B		66.7	30		110	1.138
C	20	66.7	45	131.7	120	.911
v_1	70	266.7	75			
v^*	60	250	80			

(c) The completed table for year 1.

The RAS adjustment is applied to the reduced matrix as in the illustration of the simple RAS method and when a solution is obtained the exogenous cell value of 40 is entered in the result to form the final table.

Supply	Usage			Intermediate usage u^*	Final demand	Total supply
	A	Industry	C			
Commodity A	42.7	117.3	0	160	10	200
	40	73.7	36.3	150	250	400
	17.3	59.0	43.7	120	180	300
Intermediate usage v^*				430	470	900
Primary inputs				470		
Total usage q				900

APPENDIX D

IMPORTS (INCLUDING 'NON-CLASSIFIABLE' IMPORTS) TREATED AS COMPLEMENTARY

This appendix shows the 1989-90 classification of complementary imports with a value of \$1 million or more at the foreign trade level. This corresponds to a value of \$10 million or more at the IOCC level.

CLASSIFICATION OF COMPLEMENTARY IMPORTS

1989-90 IOCC group	Foreign trade item	Balance of Payments item	Description	Value cif (\$million) 1989-90
01.06	0901.11		Coffee, not roasted, not decaffeinated	72.3
01.06	0901.12		Coffee, not roasted, decaffeinated	5.0
01.06	4001.10		Natural rubber—latex without added synthetic latex	2.1
01.06	4001.22		— excluding latex	41.6
01.06	4001.29		— crepe, not smoked	1.7
01.06	4001.30		Natural gums	2.2
32.01	8711.10		Motor cycles (incl. mopeds) and cycles fitted with an auxiliary motor	
			— cylinder capacity not exceeding 50cc	3.3
32.01	8711.20		Motor cycles (incl. mopeds)	
			— cylinder capacity exceeding 50cc, but not exceeding 250cc	52.8
32.01	8711.30		Motor cycles — cylinder capacity exceeding 250cc, but not exceeding 500cc	18.8
32.01	8711.40		— cylinder capacity exceeding 500cc, but not exceeding 800cc	18.6
32.01	8711.50		— cylinder capacity exceeding 800cc	34.2
Non- classifiable commodities	9999.10		Transactions and commodities not classified according to kind (Tariff Items with Government Nature of Entry)	439.1
	9999.40		Transactions and commodities not classified according to kind (Tariff Items with Concessional Nature of Entry)	18.2
	5(a)		Travel (part)—purchases overseas by Australian residents	1,319.0
	6.1		Australian government—official services (part)	108.0
	6.2		—other (part)	38.0

(a) This item is expenditure overseas by Australian residents less expenditure in Australia of foreign residents.

APPENDIX E

RECONCILIATION OF INPUT-OUTPUT WITH NATIONAL INCOME AND EXPENDITURE ESTIMATES : DIFFERENCES OF DEFINITION AND ESTIMATION METHODS (a)

Description	Definition (b)	Input-Output item code	Differences
Wages, salaries and supplements	<p>Payments by producers to their employees in the nature of wages and salaries, including adjustments for income in kind together with supplements to wages and pay and allowances of members of defence forces. Employees cover all persons engaged in the activities of incorporated business units and in the production of government services and services of non-profit organisations, members of the defence forces, and all persons engaged in the activities of unincorporated enterprises except the proprietors and unpaid members of the family. To be consistent with the definition of the labour force, payments to trainee teachers are excluded from estimates of wages and salaries. Supplements consist of employers' contributions to pension and superannuation funds, direct payments of pensions and retiring allowances by employers, and amounts paid as workers' compensation for injuries. Employers' contributions to pensions and superannuation funds, in general, reflect the accruing liability to employees. Some Government organisations contribute to their superannuation funds only as payments of benefits are made. In such cases it would be proper to impute payments as the liability accrues. This has not been done in these estimates except in respect of the Postal and Telecommunications Commissions where, in their commercial accounts, the accruing liability is debited as a working expense. Pay and allowances of members of the defence forces consist of active pay, field subsistence and dependants' allowances and the value of food, clothing, etc., supplied in kind. They include deferred pay but exclude war gratuities which are included in personal benefit payments to residents.</p>	P1	<p>Definition: Identical</p> <p>Estimate: The difference occurs mainly because, for industries covered by economic censuses, input-output estimates are based on data collected in those censuses rather than on the sources used for the national income and expenditure accounts.</p>
Gross operating surplus	<p>The operating surplus, before deduction of consumption of fixed capital, dividends, interest, royalties and land rent, and direct taxes payable, but after deducting stock valuation adjustment of all enterprises from operations in Australia. It is the excess of gross output over the sum of intermediate consumption, wages, salaries and supplements, and indirect taxes less subsidies. Gross operating surplus includes third party motor vehicle and public risk insurance claims paid to persons in respect of policies taken out by enterprises. Trading enterprises include all companies, public enterprises, partnerships and self-employed persons engaged in the production of goods and services for sale, but exclude financial enterprises. All dwellings are included whether let or occupied by the owner. Public trading enterprises are government undertakings which attempt to cover all, or a substantial part, of their costs through charges made to the public for the sale of goods and services. Trading enterprises' gross operating surplus is shown separately for private corporate enterprises, unincorporated enterprises, dwellings owned by persons, and public enterprises. The gross operating surplus of general government is equal to general government consumption of fixed capital. Financial enterprises comprise banks, insurance offices, superannuation funds and other enterprises primarily engaged in incurring liabilities and acquiring financial assets in the market. The gross operating surplus of financial enterprises includes an imputed bank service charge which represents a reclassification of a part of interest receipts as a charge for organising finance, in contrast to a pure interest element. The imputed bank service charge is not allocated among customers (which would have the effect of reducing their respective operating surpluses), but is shown in the production account as a negative adjustment to operating surpluses generally.</p>	P2	<p>Definition: The difference that occurs relates to the treatment of the imputed bank service charge. In the input-output tables the charge is specifically allocated to industries; in the national income and expenditure accounts it is allocated to a nominal industry. (Refer to paragraph 96 of explanatory notes.)</p> <p>Estimate: The difference occurs for the above definitional reason and because, for industries covered by economic censuses, input-output estimates are based on data collected in those censuses rather than on the sources used for the national income and expenditure accounts.</p>

(a) A reconciliation of comparable flows in the two series is provided in Tables 19 and 20.

(b) Source : *Australian National Accounts, National Income and Expenditure, 1991-92 (5204.0), pp105-111*

RECONCILIATION OF INPUT-OUTPUT WITH NATIONAL INCOME AND EXPENDITURE ESTIMATES : DIFFERENCES OF DEFINITION AND ESTIMATION METHODS (a)-continued

Description	Definition (b)	Input-Output item code	Differences
Indirect taxes less subsidies	Indirect taxes are taxes assessed on producers, i.e. enterprises and general government, in respect of the production, sale, purchase or use of goods and services, which are charged to the expenses of production. Subsidies consist of all grants made by general government to enterprises and which are credited to their production accounts. These grants may take the form of bounties on goods produced or inputs used, payments to ensure a guaranteed price or to enable maintenance of prices of goods or services below cost of production, and other forms of assistance to producers. Also included as subsidies are the amounts paid to the Australian Wheat Board under Section 46 of the Wheat Marketing Act 1979, to offset the additional cost of borrowing commercially rather than from the Reserve Bank of Australia. Payments to public trading enterprises to compensate for recurring losses are included; however payments to public trading enterprises are not paid in the same year as that in which the taxed goods are produced. In these cases the indirect taxes are estimated on a payable basis and shown on that basis in the Domestic Production Account and the General Government Income and Outlay Account. Following the introduction of a fringe benefits tax, receipt of these payments is also adjusted to a payable basis. Refunds to wheat growers of amounts previously paid into the Wheat Finance Fund and earlier price stabilisation schemes have been treated as negative indirect taxes and recorded in the year in which the refunds were made. Similarly, refunds to wool growers of the additional 5 per cent Wool Tax paid into the Market Support Fund in prior years have been recorded as negative indirect taxes in the years in which the refunds were made.	P3 P4 P7	Definition: The sum of P3, P4 and P7 is definitionally identical to the indirect taxes less subsidies shown in the national income and expenditure accounts. Estimate: The main difference occurs because input-output estimates of duty on imports are based on foreign trade data rather than the source used in the national income and expenditure accounts.
Sales by final buyers		P5	This item is not separately shown in the national income and expenditure accounts. It is described in paragraph 100 of the explanatory notes to this publication.
Imports of goods and services	The value of goods imported and amounts payable to non-residents for the provision of services to residents.	P6	Definition: The sum of items P6A and P6B is definitionally similar to the item imports of goods and services shown in the national income and expenditure accounts. The main difference occurs because of the treatment of freight and insurance provided by residents in respect of imports. The input-output tables record imports c.i.f. whereas the national income and expenditure accounts record imports f.o.b. The difference between the total value of imports of goods and services on a c.i.f. and f.o.b. basis is equal to the value of freight and insurance provided by residents in respect of imports. This freight and insurance is included in estimates of imports c.i.f. but excluded from imports f.o.b. When imports are recorded on a c.i.f. basis the value of freight and insurance provided by residents on imports must also be added to exports so as to avoid recording the balance of trade in goods and services incorrectly. Estimate: The main difference in the estimates results from the definitional difference.

(a) A reconciliation of comparable flows in the two series is provided in Tables 19 and 20.

(b) Source : *Australian National Accounts, National Income and Expenditure, 1991-92 (5204.0), pp105-111.*

RECONCILIATION OF INPUT-OUTPUT WITH NATIONAL INCOME AND EXPENDITURE ESTIMATES : DIFFERENCES OF DEFINITION AND ESTIMATION METHODS (a)-continued

Description	Definition (b)	Input-Output item code	Differences
Private final consumption expenditure	Net expenditure on goods and services by persons and expenditure of a current nature by private non-profit institutions serving households. This item excludes purchases of dwellings by persons and capital expenditure by unincorporated businesses and non-profit institutions (included in gross fixed capital expenditure), and maintenance of dwellings (treated as intermediate expenses of private enterprises), but includes personal expenditure on motor vehicles and other durable goods and the imputed rent of owner-occupied dwellings. The value of food produced and consumed on farms is included and the payment of wages and salaries in kind (e.g. food and lodgings supplied free to employees) is counted in both household income and private final consumption expenditure. Goods and services purchased by businesses or general government, e.g. as expense account allowances to employees, are excluded.	Q1	Definition: Identical Estimate: The difference occurs mainly because estimates included in the input-output tables are finalised after a detailed balancing of the supply and usage of commodities; this is a procedure which is not generally applied in finalising estimates in the national income and expenditure accounts. The estimates included in the input-output tables are internally consistent with all other commodity flows shown in the tables; however, this internal consistency does not necessarily imply a greater accuracy of the estimate of private final consumption expenditure than that obtained for the comparable estimate included in the national income and expenditure accounts. 28
Government final consumption expenditure	Net expenditure on goods and services by public authorities, other than those classified as public enterprises, which does not result in the creation of fixed tangible assets or in the acquisition of land and existing buildings or second-hand capital goods. It comprises expenditure on wages, salaries and supplies (other than those charged to capital works, etc.) and goods and services (other than fixed assets and stocks) and consumption of fixed capital. Included as supplements to wages and salaries are superannuation pensions and lump sums paid directly to former employees and contributions to superannuation funds less amounts received from employees' superannuation funds or other employers in respect of superannuation. Expenditure on repair and maintenance of roads is included. Fees, etc., charged by general government bodies for goods sold and services rendered are offset against purchases. Net expenditure overseas by general government bodies and purchases from public enterprises are included. All expenditure on defence is classified as final consumption expenditure. Net expenditure overseas on major items of defence equipment is included in the period the equipment is delivered. The adjustment to final consumption expenditure comprises deliveries of major items of defence equipment procured overseas less payments for such equipment. The value of military equipment and facilities transferred to civilian use or to overseas countries as gifts is offset against expenditure on defence.	Q2	Definition: The difference that occurs relates to the treatment of the imputed bank service charge. In the input-output tables a component of the service charge is treated as an item of expenditure of general government. In the national income and expenditure accounts the full value of the imputed bank service charge is allocated to a nominal industry. (Refer to paragraphs 95 and 104 of explanatory notes.) Estimate: The difference occurs for the above definitional reason.

(a) A reconciliation of comparable flows in the two series is provided in Tables 19 and 20.

(b) Source : *Australian National Accounts, National Income and Expenditure*, 1991-92 (5204.0), pp105-111.

RECONCILIATION OF INPUT-OUTPUT WITH NATIONAL INCOME AND EXPENDITURE ESTIMATES : DIFFERENCES OF DEFINITION AND ESTIMATION METHODS (a)-continued

Description	Definition (b)	Input-Output item code	Differences
Gross fixed capital expenditure - private	Expenditure on fixed assets shown under the headings dwellings, non-dwelling construction, equipment and real estate transfer expenses. The equipment category includes plant, machinery, equipment, vehicles, etc. Expenditure on repair and maintenance of fixed assets is excluded, being chargeable to current account. Additions are regarded as capital expenditure. Expenditure on dwellings, non-dwelling construction and equipment is measured as expenditure on new and secondhand assets, less sales of existing assets. Real estate transfer expenses comprise stamp duty, real estate agents' fees and sales commissions, conveyancing fees and miscellaneous government charges.	Q3	Definition: Identical Estimate: A difference occurs because estimates included in the input-output tables are finalised after a detailed balancing of the supply and usage of commodities, a procedure which is not generally applied in finalising estimates in the national income and expenditure accounts. The estimates included in the input-output tables are internally consistent with all other commodity flows shown in the tables; however, this internal consistency does not necessarily imply a greater accuracy of the estimate of private gross fixed capital expenditure than that obtained for the comparable estimate included in the national income and expenditure accounts.
Gross fixed capital expenditure - public enterprises	Expenditure on new fixed assets plus net expenditure on second-hand fixed assets and including both additions and replacements. Also included are wages and salaries paid by public enterprises in connection with capital works.	Q4	Definition : Identical Estimate : Identical
Gross fixed capital expenditure - general government	Expenditure on new fixed assets plus net expenditure on second-hand fixed assets whether for additions or replacements, other than for defence purposes. Expenditure on new road works (or upgrading existing roads) is included but expenditure on road repair and maintenance is classified as government final consumption expenditure.	Q5	Definition : Identical Estimate : Identical
Increase in stocks	The increase in stocks held by enterprises and general government. The increase in stocks is obtained after adjusting the increase in book value of stocks by the stock valuation adjustment. The need for a stock valuation adjustment arises because the increase in the value of stocks as calculated from existing business accounting records does not meet national accounting requirements. For national accounting purposes, physical changes in stocks should be valued at the prices current at the times when the changes occur. The stock valuation adjustment is the difference between the increase in (book) value of stocks and the physical changes valued at current prices.	Q6	Definition: Identical. (It should be noted, however, that in input-output tables stocks are classified by commodity in Tables 2, 3 and 4 and by the industries producing those commodities in Tables 5 to 18 regardless of which industry is holding the stocks (i.e. regardless of whether the holding industry is that of the producer, wholesaler, retailer or intermediate user). In the national income and expenditure accounts, stocks are classified to the industry holding the stocks.) Estimate: The difference occurs mainly because, for industries covered by economic censuses, input-output estimates are based on data collected in those censuses rather than on the sources used for the national income and expenditure accounts.

(a) A reconciliation of comparable flows in the two series is provided in Tables 19 and 20.

(b) Source : *Australian National Accounts, National Income and Expenditure, 1991-92 (\$204.0), pp.05-11*

RECONCILIATION OF INPUT-OUTPUT WITH NATIONAL INCOME AND EXPENDITURE ESTIMATES : DIFFERENCES OF DEFINITION AND ESTIMATION METHODS (a)-continued

<i>Description</i>	<i>Definition (b)</i>	<i>Input-Output item code</i>	<i>Differences</i>
Statistical discrepancy	The difference between the sum of estimates of gross domestic product and imports of goods and services on the one hand and the sum of the estimates of components of gross national expenditure and exports of goods and services on the other hand.	NIL	This item does not appear in input-output tables. The tables are finalised after a detailed balancing of the supply and usage of all goods and services between categories defined in the input-output tables. The adoption of this procedure does not necessarily imply that estimates of the other items are more accurate in input-output tables than in the national income and expenditure accounts.
Exports of goods and services	The value of goods exported and amounts receivable from non-residents for the provision of services by residents.	Q7	Definition : Refer to Imports of goods and services. Estimate : Refer to Imports of goods and services.

(a) A reconciliation of comparable flows in the two series is provided in Tables 19 and 20.

(b) Source : *Australian National Accounts, National Income and Expenditure, 1991-92* (5204.0), pp105-111.

APPENDIX F

RELEASE OF DATA ON MAGNETIC TAPE AND FLOPPY DISK

This paper provides information about the 1989-90 Input-Output data available for release on floppy disk. An order form is included.

Basic Tables

- 1 Make matrix—output by commodity group by industry
- 2 Absorption matrix—input by industry and final demand category and supply by commodity group
- 3 Imports matrix—supply by commodity group and inputs by industry and final demand category
- 4 Reconciliation of flows at basic values and at purchasers' prices by commodity group

Industry By Industry Tables (Basic Values, Recording Intra-industry Flows)

109 Industries

- Direct allocation of competing imports
- 5 Flow matrix
- 6 Direct requirements coefficients from Table 5
- 7 Total requirements coefficients from Table 6
- Indirect allocation of competing imports
- 8 Flow matrix
- 9 Direct requirements coefficients from Table 8
- 10 Total requirements coefficients from Table 9

28 Industries

- Direct allocation of competing imports
- 11 Flow matrix
- 12 Direct requirements coefficients from Table 11
- 13 Total requirements coefficients from Table 12
- Indirect allocation of competing imports
- 14 Flow matrix
- 15 Direct requirements coefficients from Table 14
- 16 Total requirements coefficients from Table 15

Primary Input Tables

- 17 Primary input content (total requirements) per \$100 of final demand by industry
- 18 Primary input content (total requirements) by industry of each category of final demand

Margin Matrices

Supply of margin by commodity group to which the margin applies and input of margin by industry and final demand category

- 19 Wholesale trade (47.01, part)
- 20 Retail trade (48.01, part)
- 21 Road transport (51.01, part)

- 22 Railway transport (52.01, part)
- 23 Water transport (53.01, part)
- 24 Air transport (54.01, part)
- 25 Marine insurance (61.04, part)
- 26 Restaurants, hotels and clubs (92.01, part)
- 27 Commodity taxes (net)
- 28 Pipeline transport (52.01, part)
- 29 Port handling (57.01, part)

Tables 19 to 29 show, for each commodity group, sales by final buyers, complementary imports and re-exports, the usage of each margin by industry and final demand category. These tables are commonly referred to as *margin matrices*. They are subject to significant limitations. Users of the tables should take particular note of the qualifications referred to in the following paragraph.

The availability of information from which estimates of margin flows can be made, both in total and by component, is severely limited. These limitations cannot be overcome by methodological developments and require that the margin data supplied on magnetic tape and floppy disk be significantly qualified: the margin matrices do not conform to the usual standards of accuracy set by the ABS in its publications.

They are being made available because of their importance for some uses of input-output tables. For example, many applications of input-output analysis involve postulating a change in the level of final demand and analysing the effect of this change on the level of output of industries and on the level of imports. The information available about final demand is generally expressed in terms of *purchasers' prices*; however, the flow and coefficient tables used to analyse this demand are valued at *basic values*. Therefore, in order to enable the change to be analysed, information enabling the postulated level of final demand to be adjusted from *purchasers' prices* to *basic values* is required. A summary reconciliation of flows valued at *purchasers' prices* and at *basic values* is given in Table 4 and details of the margin flows shown in this table are provided in the margin matrices.

In Table 4, data about the usage of margin by all industries is aggregated into the column *Intermediate Usage*, while each final demand category is shown separately. The commodity taxes (net) margin is shown separately and the other margins are shown in aggregate in the column *Margin*.

The margin matrices provide additional details about the margin flows summarised in Table 4. The matrices follow the general structure of Table 2 *Input by industry and final demand category and supply by commodity group* (Absorption matrix), and each cell in each margin matrix relates to a cell in Table 2. A cell in Table 2 shows the usage at *basic values* of a commodity group by an industry or a final demand category (for example, usage of *milk products* (21.02)

by the *confectionery and cocoa products* (21.07) industry or in private final consumption expenditure); the comparable cell in each of the margin matrices shows the margin applying to that basic value flow.

Estimation of the margin matrices involved two broad steps. First, for each margin type, the value of the margin flow relating to each non-margin commodity in the input-output system (there are approximately 1200 such commodities) was estimated. Second, each of these values, generally, was allocated to each final demand category and to each industry in proportion to the sectors' estimated usage of the non-margin commodity. The results of the application of this mechanical procedure were modified. For example, retail margin was allocated predominantly to private final consumption expenditure and no commodity taxes (net) were associated with the usage of commodities by the industry to which they are primary (i.e. flows shown in the cells on the diagonal of Table 2).

The total usage of each margin by each industry and final demand category shown in the margin matrices (i.e. the column totals of each margin matrix) are incorporated in Table 2. It should be noted that the

values in the rows of the published commodity groups containing the margin commodities (47.01, 48.01, 51.01, etc) are generally greater than the corresponding column total in the margin matrices. This difference occurs because non-margin commodities are included in each of the commodity groups (for example, a *passenger service* commodity is included in the *air transport* (54.01) commodity group).

Floppy disk characteristics and format

Input-Output tables are available as spreadsheets suitable for most popular microcomputer software packages. When ordering, please specify your software package, microcomputer disk size and density.

CONDITIONS OF SALE FOR ABS PRODUCTS

The Australian Bureau of Statistics (ABS) products are sold by the Commonwealth of Australia ("The Commonwealth") through the ABS. Prices are subject to change without notice.

COPYRIGHT

- **The Commonwealth holds the copyright of ABS products.** The Client agrees not to copy or otherwise reproduce the product or any information contained within it for the benefit of third parties, other than as allowed by these Conditions of Sale, without the prior written consent of the Commonwealth
- Where such consent is sought the Commonwealth reserves the right to set an appropriate charge or to require a revenue sharing arrangement.
- The Client is permitted to quote selected statistical data contained in the products, providing that:
 - the ABS is cited as the source of the data used;
 - the terminology used is that used by the ABS for describing data; and
 - any analysis or transformation of the data is not attributed to the ABS.
- In respect of any data in computer readable form, or software, the Commonwealth authorises the Client to use the data or software on a non-transferable and non-exclusive basis. Copying of data or software for purposes other than back-up is prohibited.

WARRANTY

- Except where required by law, no conditions or warranties, either express or implied, are given or offered for the products sold pursuant to the Client's order nor does the Commonwealth warrant the suitability of these products for any purpose. The Commonwealth shall not be liable for any damage,

injury or loss arising or resulting, directly or indirectly from the Client's use of any of these products.

- Neither the Commonwealth or the ABS nor their servants or agents shall be liable to the Client for any loss or damage arising or resulting directly or indirectly from any statement, information or advice made or given, whether negligently or otherwise, in relation to any product, its compilation or production, or the use to which it is intended to be put and without limiting the generality of the foregoing, any liability for faulty material or inaccuracies in the basic data or the physical condition of the product is expressly negated.
- Where the data is provided by the ABS on magnetic media, due care will be taken in preparation and handling. However, deterioration may occur between the time of copy and the time of receipt by the Client. Accordingly, if the data or software is unreadable on receipt and this is reported to the ABS within 28 days, it will be recopied free of charge.

LIMITATION OF LIABILITY OF THE COMMONWEALTH

Where, but for the operation of the above, the Commonwealth would incur liability in respect of any damage, injury or loss suffered from the use of any of the proprietary products, the Commonwealth will at its discretion either:

- Replace the product or the supply of an equivalent product; or
- Pay the Client an amount not exceeding \$100.

APPLICABLE LAW

This Agreement shall be construed in accordance with the law of the Australian Capital Territory and the parties submit to the jurisdiction of the courts of that Territory.

For more information ...

The ABS publishes a wide range of statistics and other information on Australia's economic and social conditions. Details of what is available in various publications and other products can be found in the *ABS Catalogue of Publications and Products* available at all ABS Offices (see below for contact details).

Information Consultancy Service

Information tailored to special needs of clients can be obtained from the Information Consultancy Service available at ABS Offices (see Information Inquiries below for contact details).

National Dial-a-Statistic Line

0055 86 400

(Steadycom P/L premium rate 25c/21.4 secs.)

This number gives 24-hour access, 365 days a year for a range of statistics.

Electronic Data Services

Selections of most frequently requested statistics are available, updated daily, on DISCOVERY (Key *656#). For more details on electronic data services available, contact Information Services in any of the ABS Offices (see Information Inquiries below for contact details).

Bookshops and Subscriptions

There are over 400 titles of various publications available from ABS bookshops in all ABS Offices (see below Bookshop Sales for contact details). The ABS also provides a subscription service through which nominated publications are provided by mail on a regular basis at no additional cost (telephone Publications Subscription Service toll free on 008 02 0608 Australia wide).
