## CHAPTER II.

## PHYSIOGRAPHY.

## § 1. General Description of Australia.

1. Geographical Position.-(i) General. The Australian Commonwealth, which includes the island continent of Australia proper and the island of Tasmania, is situated in the Southern Hemisphere, and comprises in all an area of about $2,974,58 \mathrm{r}$ square miles, the mainland alone containing about $2,948,366$ square miles. Bounded on the west and east by the Indian and Pacific Oceans respectively, it lies between longitudes $113^{\circ} 9^{\prime} \mathrm{E}$. and $153^{\circ} 39^{\prime} \mathrm{E}$., while its northern and southern limits are the parallels of latitude $10^{\circ} 4 \mathrm{I}^{\prime} \mathrm{S}$. and $39^{\circ} 8^{\prime} \mathrm{S}$., or, including Tasmania, $43^{\circ} 39^{\prime} \mathrm{S}$. On its north are the Timor and Arafura Seas and Torres Strait-on its south the Southern Ocean and Bass Strait. The extreme points are "Steep Point" on the west, "Cape Byron" on the east, "Cape York" on the north, "Wilson's Promontory " on the south, or, if Tasmaniabe included, "South-East Cape."
(ii) Tropical and Temperate Regions. Of the total area of Australia nearly 40 per cent. lies within the tropics. Assuming, as is usual, that the latitude of the Tropic of Capricorn is $23^{\circ} 30^{\prime} \mathrm{S}$. (its mean value for 1937 was $23^{\circ} 26^{\prime} 50.70^{\prime \prime}$ ), the areas within the tropical and temperate zones are approximately as follows :-

## AUSTRALIA-AREAS OF TROPICAL AND TEMPERATE REGIONS.

(States and Territory Parttally within Tropics.)

| Area, | Qucenisland. | Western <br> Australiz. | Northern Territory. | Total. |
| :---: | :---: | :---: | :---: | :---: |
|  | Sg. Milcs. | Si. Miles. | Sq. Miles | Sq. Miles. |
| Within Tropical Zone | 359,000 | 364,000 | 426,320 | 1,149,320 |
| Within Temperate Zone | 311,500 | 611,920 | 97,300 | 1,020,720 |
| Ratio of Tropical part to whole State. | 0.535 | 0.373 | 0.814 | 0.530 |
| Ratio of Temperate part to whole State | 0.465 | 0.627 | 0.186 | 0.470 |

Thus the tropical part is roughly about one-half ( 0.530 ) of the three territories mentioned above, or about five-thitteenths of the whole of Australia ( 0.386 ).
2. Area of Australia compared with Areas of other Countries.-It is not always realized that the area of Australia is almost as great as that of the United States of America, four-fifths of that of Canada, more than one-fifth of the area of the British Empire, nearly three-fourths of the whole area of Europe, and about 25 times as large
as Great Britain and Ireland. This great area, coupled with a limited population, renders the solution of the problem of Australian development a particularly difficult one. The areas of Australia and of certain other countries are given in the following table :-

AREA OF AUSTRALIA AND OF OTHER COUNTRIES, Circa 1936.

| Country. | Area. | Country. | Area. |
| :---: | :---: | :---: | :---: |
| Continental Divisions- | Sq. miles. | Afriea-continued. | Sq. miles. |
| Europe | 4,412,000 | Angola | 488,000 |
| Asia | 16,047,000 | Union of South Africa | 472,000 |
| Africa | I1,560,000 | Egypt | 386,000 |
| North and Central America and West Indies |  | Tanganyika Territory | 374,000 |
| South America . . |  | Abyssinia | 347,000 |
| Total, exclusive of Arctic |  | Mozambique . | 298,000 |
| and Antarctic Conts... | 51,147,000 | Northern Rhodesia | 288,000 |
| Europe- |  | Bechuanaland Protectorate | 275,000 |
| Soviet Union (Russia) | 2,316,000 | Madagascar . $\quad$. | 238,000 |
| France | 213,000 | Kenya Colony and Protec- |  |
| Spain (inc. possessions) | 194,000 |  |  |
| Germany .. | 182,000 | Other . . | 1,385,000 |
| Sweden | 173,000 | Total .. .. | 11,560,000 |
| Poland | 150,000 | North and Central America- |  |
| Finland | 150,000 | Canada | 3,684,000 |
| Norway | 125,000 | United States of America. | 3,027,000 |
| Italy .- | 120,000 | Mexico | 760,000 |
| Rumania | 114,000 | Alaska | 587,000 |
| Yugoslavia . . . | 96,000 | Newfoundland and Labra- |  |
| Great Britain and Northern |  | dor | 163,000 |
| Ireland | 94,000 | Nicaragua | 49,000 |
| Other | 485,000 | Other .. | 392,000 |
| Total | 4,412,000 | Total | 8,662,000 |
| Asia- |  | South America- |  |
| Soviet Union (Russia) . . | 5,860,000 | Brazil |  |
| China and Dependencies .. | 4,287,000 | Argentine Republic | 3,286,000 |
| British India and Adminis- |  | Argentine Republic Bolivia | $1,078,000$ 515,000 |
| Arabia and Autonomous |  | Peru | 482,000 |
| States | 1,004,000 | Colombia (exc. of Panama) | 449,000 |
| Feudatory Indian States | 712,000 | Venezuela | 352,000 |
| Iran . . | 634,000 | Chile .. | 286,000 |

| French West Africa | 1,8.5,000 | Territory of New Guinea. . | 104,015 93,000 |
| Anglo-Egyptian Sudan | 973,000 | Papua | $\begin{aligned} & 93,000 \\ & 90,540 \end{aligned}$ |
| Belgian Congo . ${ }^{\text {a }}$. | 921,000 | Other .. | 38,500 |
| Jrench Equatorial Africa | S71,000 S5S,000 | Total | 3,461,636 |
| $\begin{array}{ll}\text { Algeria } \\ \text { Tibya . . } & \end{array}$ | $\begin{aligned} & 858,000 \\ & 685,000 \end{aligned}$ | British Empire | 13.353,426 |
| dibya | 685,000 | British Empire | 13,353,426 |

The figures quoted in the table have been extracted from the Statistical Year Book of the League of Nations or the Statesman's Year Book.
3. Areas of Political Subdivisions.-As already stated, Australia consists of six States and the Northern and Australian Capital Territories. The areas of these, and their proportions of the total of Australia, are shown in the following table :-

AUSTRALIA-AREA OF STATES AND TERRITORIES.

4. Coastal Configuration.-(i) General. There are no striking features in the configuration of the coast ; the most remarkable indentations are the Gulf of Carpentaria on the north, and the Great Australian Bight on the south. The Cape York Peninsula on the extreme north is the only other remarkable feature in the outline. In Year Book No. I, an enumeration of the features of the coast-line of Australia was given (see pp. 60 to 68).
(ii) Coast-line. The lengths of coast-line, exclusive of minor indentations, of each State and of the whole continent, and the area per mile of coast-line, are shown in the following table :-

AUSTRALIA-COAST-LINE AND AREA PER MILE THEREOF.

$$
\text { (a) Including Australian Capital Territory. } \quad \text { (b) Area } 2,948,366 \text { square miles. }
$$

For the entire Commonwealth of Australia this gives a coast-line of 12,210 miles and an average of 244 square miles for one mile of coast-line. According to Strelbitski, Europe has only 75 square miles of area to each mile of coast-line, and, according to recent figures, England and Wales have only one-third of this, viz., 25 square miles.
(iii) Historical Significance of Coastal Names. It is interesting to trace the voyages of some of the early navigators by the names bestowed by them on various coastal foatures-thus Dutch names are found on various points of the Western Australian coast, in Nuyts' Archipelago, in the Northern Territory, and in the Gulf of Carpentaria; Captain Cook can be followed along the coasts of New South Wales and Queensland; Flinders' track is easily recognized from Sydney southwards, as far as Cape Catastrophe,
by the numerous Lincolnshire names bestowed by him; and the French navigaters of the end of the eighteenth and the beginning of the nineteenth century have left their names all along the Western Australian, South Australian and Tasmanian coasts.
5. Geographical Features of Australia.-In each of the earlier issues of this Year Book fairly complete information has been given concerning some special geographical element. The nature of this information and its position in the various Year Books can be readily ascertained on reference to the special index following the index to maps and graphs at the end of this work.
6. Fauna, Flora, Geology and Seismology of Australia.-Special articles dealing with these features have appeared in previous Year Books, but limits of space naturally preclude their repetition in each volume. As pointed out in 5 supra, however, the nature and position of these articles can be readily ascertained from the special index. A reference to Barisal Guns will be found in Vol. IX., p. 56.

## § 2. Climate and Meteorology of Australia.*

1. Introductory.-In Year Book No. 3, pp. 79, 80, some account was given of the history of Australian meteorology, including reference to the development of magnetic observations and the equipment for the determination of various climatological records. In Year Book No. 4, pp. 84 and 87 , will be found a short sketch of the creation and organization of the Commonwealth Bureau of Meteorology, and a résumé of the subjects dealt with at the Meteorological Conference in 1907.
2. Meteorological Publications.-Reference to publications issued by the Central Meteorological Bureau will be found in Official Year Book No. 22, pp. 40, 4r. The following publications have since been issued:-Volume of " Results of Rainfall Observations made in Western Australia," for all years of record to 1927; Map of Normal Meteorological Conditions in Australia affecting Aviation; a Paper "A Basis for Seasonal Forecasting "; by H. A. Hunt; Bulletin No. 18, "Foreshadowing Monsoonal Rains in Northern Australia"; Bulletin No. 19, "Thunderstorms in Australia"; Bulletin No. 20, "Zones of Relative Physical Comfort in Australia"; a Paper on "Frost Risks and Frost-Forecasting"; Booklet containing Meteorological Data for certain Australian Localities; a volume of "Results of Rainfall Observations made in Tasmania"; and a volume of "Results of Rainfall Observations made in Victoria", (Supplementary volume to 1936).
3. General Description of Australia.-A considerable portion ( 0.530 ) of three divisions of Australia is north of the tropic of Capricorn-that is to say, within the States of Queensland and Western Australia, and the Northern Territory; no less than $1,149,320$ square miles belong to the tropical zone and $1,020,720$ to the temperate zone. The whole area of Australia within the temperate zone, however, is $1,825,261$ square miles; thus the tropical part is about 0.386 , or about five-thirteenths of the whole, or the "temperate" region is half as large again as the "tropical" (more accurately 1.588). By reason of its insular geographical position and the absence of striking physical features, Australia is, on the whole, less subject to extremes of weather than are regions of similar area in other parts of the globe, and latitude for latitude Australia is, on the whole, more temperate.

The altitudes of the surface of Australia range up to a little over 7,300 feet, hence its climate embraces a great many features, from the characteristically tropical to what is essentially alpine, a fact indicated in some measure by the name Australian Alps given to the southern portion of the great Dividing Range.

On the coast, the rainfall is often abundant and the atmosphere moist, but in some portions of the interior it is very limited, and the atmosphere dry. The distribution of forest, therefore, with its climatic influence, is very uneven. In the interior, in places, there are fine belts of trees, but there are large areas also which are treeless, and where the air is hot and parching in summer. Again, on the coast, even so far south as latitude $35^{\circ}$, the vegetation is tropical in its luxuriance, and to some extent also in character. Climatologically, therefore, Australia may be said to present a great variety of features.

[^0]4. Meteorological Divisions.-(i) General. Reference to the divisions adopted by the Commonwealth Meteorologist will be found in Official Tear Book No. 22, p. 4 I .
(ii) Special Climatological Stations. The latitudes, longitudes and altitudes of special stations, the climatological features of which are graphically represented hercinafter, are as follows :-

SPECIAL CLIMATOLOGICAL STATIONS-AUSTRALIA.

| Locality. | Height above Sca Level. | Latitude. <br> s . |  | Longitude. E. |  | Locality. | Heirht above Sear Level. | $\begin{gathered} \text { Latitude. }{ }^{\text {S }} \text { Songitude. } \\ \text { S. } \end{gathered}$ |  |  |  |

| Hobart | 177 |  | 53 | 147 | 20 | Coolgardie .. | 1,389 |  | 57 | 121 |  |

5. Temperatures.-(i) Comparisons with other Countries. In respect of Australian temperatures generally, it may be pointed out that the mean annual isotherm for $70^{\circ}$ Fahrenheit extends in South America and South Africa as far south as latitude $33^{\circ}$, while in Australia it reaches only as far south as latitude $30^{\circ}$, thus showing that, on the whole, Australia has latitude for latitude a more temperate climate than other places in the Southern Hemisphere.

The comparison is cven more favourable when the Northern Hemisphere is included, for in the United States the $70^{\circ}$ isotherm extends in several of the western States as far north as latitude $41^{\circ}$. In Europe, the same isotherm reaches almost to the southern shores of Spain, passing, however, afterwards along the northern shores of Africa till it reaches the Red Sea, when it bends northward along the eastern shore of the Mediterranean till it reaches Syria. In Asia, nearly the whole of the land area south of latitude $40^{\circ} \mathrm{N}$. has a higher temperature than $70^{\circ}$.

The extreme range of temperature is less than $100^{\circ}$, over practically the whole of Australia, that figure being only slightly exceeded at a very few places; it is mostly $70^{\circ}$ to $90^{\circ}$ over inland areas, and somewhat less on the coast. In parts of Asia and North America, the extreme range exceeds $130^{\circ}$ and $150^{\circ}$ in some localities.

Along the northern shores of Australia the temperatures are very equable. At Darwin, for example, the difference in the means for the hottest and coldest monthe is only $8.5^{\circ}$, and the extreme readings for the year, or the highest maximum on record and the lowest minimum, show a difference of under $50^{\circ}$
(ii) Hottest and Coldest Parts. A comparison of the temperatures recorded at coast and inland stations shows that, in Australia, as in other continents, the range increases with increasing distance from the coast.

In the interior of Australia, and during exceptionally dry summers, the temperature occasionally reaches or exceeds $120^{\circ}$ in the shade, and during the dry winters the major portion of the country to the south of the tropics is subject to ground frosts. The hottest area of the continent is situated in the northern part of Western Australia about the Marble Bar and Nullagine gold-fields, where the maximum shade temperature during the summer sometimes exceeds $100^{\circ}$ continuously for days and weeks. The coldest part of Australia is the extreme south-east of New South Wales and extreme east of Victoriathe region of the Australian Alps. Here the temperature seldom, if ever, reaches $100^{\circ}$ even in the hottest of seasons, while in winter, readings slightly below zero are occasionally recorded.

Tasmania as a whole enjoys a most moderate and equable range of temperature throughout the year, although occasionally hot winds may cross the Straits and cause the temperature to rise to $100^{\circ}$ in the low-lying parts.
(iii) Monthly Maximum and Minimum Temperatures. The normal monthly maximum and minimum temperatures can be best shown by means of graphs, which cxhibit the nature of the fluctuation of each for all available years. In the diagram herein for nino representative places in Australia, the upper heavy curves show the mean maximum, and the lower heavy curves the mean minimum temperatures based upon daily observations, while the other curves show the humidities.
6. Humidity.-After temperature, humidity is the most important element of climate, as regards its effect on human comfort, rainfall supply, and in connexion with engineering problems.

In this publication the absolute humidity has been graphically represented in inches of vapour pressure (i.e., that portion of the barometric pressure due to vapour). It is this total quantity of moisture in the air which affects personal comfort, plays an important part in varying the density of the atmosphere, and in heating and refrigerating processes. The more commonly quoted value, called the relative humidity, refers to the ratio which the actual moisture content of the air bears to the total amount possible if saturation existed at the given temperature, and is usually quoted as a percentage. The relative humidity is an important factor in all drying operations, but is much less important than the absolute humidity as affecting animal life.

The mean monthly vapour pressure has also been added to the tables of climatological data for the capital cities included herein.

The normal monthly values of vapour pressure, it should be noted, combine to make the annual curve for this element which is comparable with the maximum and minimum temperature curves, but the relative humidities consisting as they do of the extremes for each month do not show the normal annual fluctuation which would be approximately midway between the extremes.

The order of stations in descending values of 9 a.m. vapour pressure is Darwin, Brisbane, Sydney, Perth, Melbourne, Adelaide, Canberra, Hobart and Alice Springs, while the relative humidity diminishes in the order, Sydney, Canberra, Melbourne, Darwin, Hobart, Brisbane, Perth, Adelaide and Alice Springs.
7. Evaporation.-(i) General. The rate and quantity of evaporation in any territory is influenced by the prevailing temperature, and by atmospheric humidity, pressure and movement. In Australia, the question is of perhaps more than ordinary importance, since in its drier regions water has often to be conserved in "tanks"* and dams. The magnitude of the economic loss by evaporation will be appreciated from the tabular records herein, which show that the vearly amount varies from about 31 inches at Hobart to more than roo inches in the Central parts of Australia. Over the inland districts of the continent it has been calculated that evaporation equals the rainfall where the annual totals are about 36 inches, the variations above and below this quantity being inverse.
(ii) Monthly Evaporation Curves. The diagrams herein showing the mean monthly cvaporation in various parts of Australia disclose how characteristically different are the amounts for the several months in different localities.
(iii) Loss by Evaporation. In the interior of Australia the possible evaporation is greater than the actual rainfall. Since the loss by evaporation depends largely on the exposed area, tanks and dams so designed that the surface shall be a minimum are advantageous. Further, the more protected from the direct rays of the sun and from winds by means of suitable tree planting, the less will be the loss by evaporation. These matters are naturally of more than ordinary concern in the drier districts of Australia.
8. Rainfall-(i) General. The rainfall of any region is determined mainly by the direction and route of the prevailing winds, by the varying temperatures of the earth's surface over which they blow, and by its physiographical features.

Australia lies within the zones of the south-east trades and prevailing westerly winds. The southern limit of the south-east trade strikes the eastern shores at about $30^{\circ}$ south latitude, and, with very few exceptions, the heaviest rains of the Australian

[^1]continent are procipitated along the Pacific slopes to the north of that latitude, the varying quantities being more or less regulated by the differences in elevation of the shores and of the chain of mountains upon which the rain-laden winds blow from the New South Wales northern border to Thursday Island. The converse effect is exemplified on the north-west coast of Western Australia, where the prevailing winds blowing from the interior of the continent instead of from the ocean, result in the lightest coastal rain in Australin.

The westerly winds, which skirt the southern shores, are responsible for the reliable, generally light to moderate rains enjoyed by the south-western portion of Western Australia, by the agricultural areas of South Australia, by a great part of Victoria, and by the whole of Tasmania.
(ii) Distribution of Rainfall. The average annual rainfall map of Australia herein shows that the heaviest yearly falls-over 50 inches-occur over the coastal region of the Northern Territory, over most of the Cape York Peninsula and coastal districts of Queensland, over many of the coastal areas of New South Wales, and the western parts of Tasmania. A great part of the interior of the continent, stretching from the far west of New South Wales and the south-west of Queensland to the vicinity of Shark Bay in Western Australia, has a very low average rainfall of less than to inches a year. Between these two regions of heavy and very low rainfall are the extensive areas which experience useful to good rains, and in the southern and eastern parts of which are found the best country and most of the population and primary production.
(iii) Factors Determining Occurrence, Intensity and Seasonal Distribution of Rainfall. Reference has already been made to the frequent rains occurring in the north-eastern coastal districts of Queensland with the prevailing south-east trade winds and to similar rains in the west of Tasmania with the prevailing westerly winds. Other rains in Australia are associated mainly with tropical and southern depressions.

The former chiefly affect the northern, eastern, and to some extent the central parts of the continent and operate in an irregular manner during the warmer half of the year, but principally from December to March. They vary considerably in activity and scope from year to year, occasionally developing into severe storms off the east and north-west coasts. Tropical rainstorms sometimes cover an enormous area, half of the continent on occasions receiving moderate to very heavy falls during a period of a few days. Rain is also experienced, with some regularity, with thunderstorms in tropical areas, specially near the coast. All these tropical rains, however, favour mostly the northern and eastern parts of the area referred to : the other parts further inland receive lighter, less frequent and less reliable rainfall. With the exception of districts near the east coast, where some rain falls in all seasons, the tropical parts of the continent receive useful rains only on rare occasions from May to September.

The southern depressions are most active in the winter-June to August-and early spring months. The rains associated with them are fairly reliable and frequent over Southern Australia and Tasmania, and provide during that period the principal factor in the successful growing of wheat. These depressions also operate with varying activity during the remainder of the year, but the accompanying rains are usually lighter. The southern rains favour chiefly the south-west of Western Australia, the agricultural districts of South Australia, Victoria, Tasmania, and the southern parts of New South Wales. They sometimes extend into the drier regions of the interior, but only infrequently and with irregular rains.

The map showing mean monthly distribution of rainfall over Australia gives information on the amount and occurrence of rain in graphic form.
(iv) Wettest and Driest Regions. The wettest known part of Australia is on the north-east coast of Queensland, between Port Douglas and Cardwell, where three stations situated on, or adjacent to, the Johnstone and Russell Rivers have an average annual rainfall of between 142 and 165 inches. The maximum and minimum falls there are :Goondi, 241 . 53 in 1894 and 67.88 inches in 1915, or a range of 173.65 inches; Innisfail, 211.24 in 1894 and 69.87 inches in 1902, or a range of 141.37 inches; Harvey Creek, 254.77 in 1921 and 80.47 inches in 1902, or a range of 174.30 inches.

On four occasions more than 200 inches have been recorded at Goondi, the last of these being in 1910, when 204.82 inches were registered. The record at this station covers a period of ${ }_{51}$ years.

Harvey Creek, in the shorter period of 30 years, has four times exceeded 200 inches, the total for 1921 being 254.77 inches, and at the South Johnstone Sugar Experiment Station, where a gauge was established eighteen years ago, 202.52 inches were recorded in 192 I .

In Tasmania the wettest part is in the West Coast region, the mean annual rainfall at Lake Margaret being 145.25 inches, with a maximum of 175.12 inches in 1924 .

The driest known part of the continent is in the Lake Eyre district in South Australia (the only part of the continent below sea level), where the annual average is only 5 inches, and where the fall rarely exceeds 10 inches for the twelve months.

The inland districts of Western Australia were at one time regarded as the driest part of Australia, but authentic observations in recent years over settled districts in the east of that State show that the annual average is from 10 to 12 inches.
(v) Quantities and Distribution of Rainfall. The general distribution is best seen from the rainfall map herein, which shows the areas subject to average annual rainfalls lying between certain limits. The areas enjoying varying quantities of rainfall determined from the latest available information are shown in the following table :-

## AVERAGE ANNUAL RAINFALL DISTRIBUTION.

| Average Annual Rainfall. |  | $\underset{(a)}{\text { N.S.W. }}$ | Victoria. | Queensland. | South | $\begin{aligned} & \text { Northern } \\ & \text { Territory } \end{aligned}$ | Western Australia. | $\underset{\substack{\text { Tas- } \\ \text { mania. }}}{\text { (h) }}$ (b) | Total. (b) |

| Total area |  | 310,372 | 87,884 | 670,500 | 380,070 | 523,620 | 975,920 | 23,438 | 2,971,804 |

(a) Including Australian Capital Territory. (b) Over an arca of 2,777 square miles no records are available.

Referring first to the capital cities the records of which are given in the next table, it will be seen that Sydney, with a normal rainfall of 47.53 inches, occupies the chief place; Brisbane, Perth, Melbourne, Hobart, Canberra and Adelaide follow in that order, Adelaide with 21.17 inches being the driest. The extreme range from the wettest to the driest year is greatest at Brisbane ( 72.09 inches) and least at Adelaido (19.48 inches).

In order to show how the rainfall is distributed throughout the year in various parts of the continent, the figures for representative towns have been selected. (See map.). The figures for Darwin, typical of the Northern Territory, show that nearly the whole of the rainfall occurs there in the summer months, while little or none falls in the middle of the year. The figures for Perth, as representing the south-western part of the continent, are the reverse for while the summer months are dry, the winter ones are very wet. In Melbourne and Hobart the rain is fairly well distributed throughout the twelve months, with a maximum in October for the former, and in November for the latter. The records at Alice Springs and Daly Waters indicate that in the central parts of Australia most of the rain occurs from November to March. In Queensland, the heaviest rains fall in the summer months, but good averages are also maintained during the other seasons in eastern parts.

On the const of New South Wales，the first six months of the year are the wettest， with a maximum in the autumn；the averages during the last six months are fair，and moderately uniform．Generally it may be said that approximately one－third of the area of the continent，principally in the eastern and northern parts，enjoys an annual average rainfall of from 20 to 50 or more inches，the remaining two－thirds averaging from 5 to 20 inches．
（vi）Curves of Rainfall and Evaporation．The relative amounts of rainfall and evaporation at different times through the year are clearly indicated in the graphs herein．Inspection thereof will show how large is the evaporation when water is fully exposed to the direct rays of the sun and to wind．
（vii）Tables of Rainfall．The table of rainfall for a long period of years for each of the various Australian capitals affords information as to the variability of the fall in successive years，and the list of the more remarkable falls furnishes information as to what may be expected on particular occasions．

HEAVY RAINFALLS_AUSTRALIAN CAPITAL TERRITORY, UP T0 1937, INCLUSIVE.

10. Snowfall.-Light snow has been known to fall occasionally as far north as latitude $3 I^{\circ} \mathrm{S} .$, and from the western to the eastern shores of the continent. During exceptional seasons, it has fallen simultaneously over two-thirds of the State of New. South Wales, and has extended at times along the whole of the Great Dividing Range, from its southern extremity in Victoria as far north as Toowoomba in Queensland. During the winter, for several months, snow covers the ground to a great extent on the

AVERACE ANNUAL FLUCTUATLONS OE NORXAL MAXIMUM AND MHSMUM TEMPERATURE AND HUMIDITE.

Explanation.-The upper and lower heavy lines in each graph represent the mean maximum and mean minimum temperatures respectively. The Fahrenheit temperature scales are shown on the ruter edge of the sheet under " $F$ " and the centigrade scales in the two inner columns under " $C$."

The broken line shows the normal absolute humidity in the form of 9 a.m. vapour pressures for which the figures in the outer " $F$ " columns represent hundredths of an jnch of barometric jressure.

The upper and lower fine lines join the greatest and the least monthly means of relative humidity respectively, the figures under the outer columns " $F$ " indicating percentage values.

The curves for temperature and vapour pressure joining the mean monthly values serve to show the annual fluctuation of these elements, but the relative bumidity graphs joining the extreme values for each month do not indicate any normal annual variation.

Comparison of the maximum and minimum temperature curves affords a measure of the mean diurnal range of temperature. At Perth in the middle of January, for instance, there is normally a range of $2 \mathbf{I}^{\circ}$ from $63^{\circ} \mathrm{F}$. to $84^{\circ} \mathrm{F}$., but in July it is only $15^{\circ}$ from $48^{\circ} \mathrm{F}$. to $63^{\circ} \mathrm{F}$.

The relative humidity curves Illustrate the extreme range of the mean monthly humidity over a number of ypars.

MEAN MONTHLY RAINFALL AND EVAPORATION.

Explanation.-On the preseding graphis thick lines denote rainfall, and thin lines evaporation and ehow the fluctuation of the mean rate of fall or evaporation per month throughout the year. The results, photed from the Climatological Tables herein, are shown in fuches (see the outer columns), and the corresponding metric scale (centimetres) is shown in the two inner columns. The evaporation is not given for Darwin.

At Perth. Adelaide, Mrishane. Mellourne, Hohart, Canberra, Alice Springa, and Coolgardie the results have been obtained from jacketed tanks sunk in the ground. At Sydney and Dubbo sunken tanks without water jackete are used, whilst at. Laverton (W.A.) the records are taken from a small portable jacket evaporation dish of 8 inches in diameter.

The distance for any date from the zero line to the curve represents the average number of inches, reckoned as per month, of rainfall at that date. Thus, taking the curve for Adelaide in the middle of January, the rain falls on the average at the rate of about three-fourths of an inch per month or, say, at the rate of about 9 inches per year. In the middle of dune it, falls at the rate of a little over 3 inches per month, or, say, at the rate of about 37 inches per year. At Dubbo, the evaporation is at the rate of nearly $1 \pm$ inches per montio about the middle of January, and only about $1 \frac{1}{2}$ inches at the middle of June.

The mean annual rainfall and evaporation at the places indicated are given in the appended table.

MEAN ANNUAL RAINFALL AND EVAPORATION.

| Place. | Rainfall. | Evaporation. | Place. | Rainfall. | Evaporation. |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | In. | In. |  | In. | In. |

| Hobart | 23.97 | 31.12 | Coolgardie .. | 10.17 | 85.37 |

MEAN BAROMETIRIC IRESSURE.-CAPITAL CITIES.

Explanation.-The lines representing the ycarly flurtuations of barometric pressure at the State capitai cities are means for long periods, and are plotted from the Climatological Tables herein. The pressures are shown in incbes on about $2 \frac{1}{2}$ times the natural scale, and the corresponding pressures in centimetres are also shown in the two inner colimms, in which each division represents one millimetre.

Taking the Brishane graph for purposes of illustration, it will be seen that the mean pressure in the middle of January is ahout 29.87 inches, and there are maxima in the middle of May and August of about 30.09 inches.

Area affected and period of duration of the Longest Heat Waves when the Maximum Temperahure for conseculive 24 hours reached or exceeded $100^{\circ}$ Fah.

Uireatest number of conseculive days on which the Shade Temperature was over $100^{\circ}$ Fah. at the places indicated.

$49$

Australian $A l_{p s}$, where also the temperature falls below zero Fahrenheit during the night. In the ravines around Kosciusko and similar localities the snow never entirely disappears.
II. Hail.-Hail falls most frequently along the southern shores of the continent in the winter, and over castern Australia during the summer months. The size of the hailstones generally increases with distance from the coast. A summer rarely passes without some station experiencing a fall of stones exceeding in size an ordinary hen-egg, and many riddled sheets of light-gange galvanized iron bear evidence of the weight and penetrating power of the stones.

The hailstones occur most frequently when the barometric readings indicate a flat and unstable condition of pressure. They are almost invariably associated with tomadoes or tornadic tendencies, and on the east coast the conds from which the stones fall are generally of a remarkable sepia-coloured tint.
12. Barometric Pressures.-The mean annual barometric pressure (corrected to sea-level and standard gravity) in Australia varies from 29.80 inches on the north coast to 29.92 inches over the central and 30.03 inches in the southern parts of the continent. - In January, the mean pressure ranges from 29.70 inches in the northom and central areas to 29.95 inches' in the southern. The July mean pressure ranges from 29.90 inches at Darwin to 30.11 inches at Alice Springs. Barometer readings corrected to mean sea-level and standard gravity have, under anticyclonic conditions in the interior of the continent, ranged as high as 30.78 inches (at Kalgoorlic on the 28 th July, 1901) and have fallen as low as 27.55 inches. This lowest record was registered at Nackay during a tropical hurricane on the 2 ist January, 1918. An almost equaliy abnormal reading of 27.88 inches was recorded at Innisfail during a similar storm on the 10 th March, 1918. The mean barometric pressure for the capitals of Australia is shown on the graphs herein.
13. Wind.--(i) Trade Winds. The two distinctive wind eurents in Australia are as previously stated, the south-east and westerly trade winds. As the belt of the earth's atmosphere in which they blow apparently follows the sun's ecliptic path north and south of the equator, so the area of the continent affected by these winds varies at different seasons of the year. During the summer months the anticyclonic belt travels in very high latitudes, thereby bringing the south-cast trade winds as far south as $30^{\circ}$ south latitude. The westerly trade winds retreat a considerable distance to the south of Australia, and are rarely in cvidence in the hot months. When the sun passes to the north of the equator, the south east trade winds follow it, and only operate to the north of the tropics for the greater part of the winter. The westerly winds come into lower latitudes during the same period of the year. They sweep across the southern areas of the continent from the Leeuwin to Cape Howe, and during some seasons are remarkably persistent and strong, and occasionally penetrate to almost tropical latitudes. .
(ii) Land and Sea Breeses. The prevailing winds second in order of importance are the land and sea breezes. On the east coast the sea breezes which come in from the north-east, when in full force, frequently reach the velocity of a gale during the aftemoon in the summer months, the maximum hourly velocity, ordinarily attained about 3 p.m., not Infrequently attaining a rate of 35 to 40 miles per hour. This wind, although strong, is usually shallow in depth, and does not ordinarily jenctrate more than 9 or 12 miles inland.

The land breezes on the east-coast blow out from a westerly direction during the night.
On the western shores of the continent the directions are reversed. The sea breezes come in from the south-west, and the land breezes blow out from the north-east.
(iii) Inland Winds. Inland, the direction of the prevailing winds is largely regulated by the seasonal changes of pressure. so disposed as to cause the winds to radiate spirally outward from the centre of the continent during the winter months, and to circulate spirally from the seaboard to the centre of Australia during the summer months.
(iv) Prevailing Direction at the Capital Cities. In Çanberra, the winds are mainly from easterly and north-westerly directions, the former predominating to a somewhat greater degree in the mornings, the latter in the afternoons and in the colder half of the year.

In Perth, southerly (south-west to south-east) is the prevailing direction for Augnst to April inclusive and north-north-west to north-north-east for the midwinter months.

In Adelaide the summer winds are from the south-west and south, and in the winter from north-east to north.

In Brisbane, south-east winds are in evidence all the year round, but more especially from January to April.

In Sydney from May to September the prevailing direction is westerly, and for the remaining seven months north-easterly.

Melbourne winter winds are from north-west to north-east, and those of the summer from south-west to south-east.

At Hobart the prevailing direction for the year is from north-west.
Over the greater part of Australia, January is the most windy month, i.e., is the month when the winds are strongest on the average, though the most violent wind storms occur at other times during the year, the time varying with the latitude.
14. Cyclones and Storms.-The "elements" in Australia are ordinarily peaceful, and while destructive cyclones have visited various parts, more especially coastal areas, such visitations are rare, and may be properly deseribed as erratic.

During the winter months, the southern shores of the continent are subject to cyclonic storms, evolved from the V-shaped depressions of the southern low-pressure belt. They are felt most severely over the south-western parts of Western Australia, to the south-east of South Australia, in Bass Strait, including the coast-line of Victoria, and on the west coast of Tasmania. Apparently the more violent wind pressures from these cyclones are experienced in their northern half, or in that part of them which has a north-westerly to a south-westerly circulation.

The north-east coast of Queensland is occasionally visited by hurricanes from the north-east tropics. During the first four months of the year, these hurricanes appear to have their origin in the neighbourhood of the South Pacific Islands, their path being a parabolic curve first to the S.W. and finally towards the S.F. Only a small percentage, however, reach Australia, the majority recurving in their path to the east of New Caledonia.

Very severe cyclones, locally known as " willy willies," are peculiar to the northwest coast of Western Australia from the months of November to April, inclusive. They apparently originate in the ocean in the vicinity of Cambridge Gulf, and travel- in a south-westerly direction with continually increasing force, displaying their greatest energy near Cossack and Onslow, between latitudes $20^{\circ}$ and $22^{\circ}$ South. The winds in these storms, like those from the north-east tropics, are very violent and destructive, and cause great havoc amongst the pearl-fishers. The greatest velocities are usually to be found in the south-eastern quadrant of the cyclones, with north-east to east winds. After leaving the north-west coast, these storms either travel southwards, following the coast-line, or cross the continent to the Great Australian Bight. When they take the latter course, their track is marked by torrential rains, as much as 29.41 inches, for example, being recorded in 24 hours at Whim Creek from one such occurrence. Falls of o inches and over have frequently been recorded in the northern interior of Western Australia from similar. storme.

Some further notes on severe cyclones and on " southerly bursters," a characteristic feature of the castern part of Australia, will be found in previous issues of the Official Year Book (see No. 6, pp. 84, 85, 86).

A special article dealing with " Australian Huricanes and Related Storms: appeared in Official Year Jook No. 16, pp. 80-84.
15. Influences affecting Australian Climate.-(i) General. Australian history does not cover a sufficient period, nor is the country sufficiently occupied, to ascertain whether or not the advance of settlement has materially affected the climate as a whole. Local changes have, however, taken place, a fact which suggests that settlement and the treatment of the land have a distinct effect on local conditions. For example, the mean temperature of Sydney shows a rise of two tenths of a degree during tho last twenty years, a change probably brought about by the great increase of residential and manufacturing buildings within the city and in the surrounding suburbs. Again, low-lying lands on the north coast of New South Wales, which originally were seldom subject to frosts, have, with the denudation of the surrounding hills from forests, experienced annual visitations, the probable explanatior being that through the absence of trees the cold air of the high lands now flows unchecked and untempered down the sides of the hills to the valleys and lower lands.
(ii) Influence of Forests on Climaie. As already indicated, forests doubtless exercise a great influence on Jocal climate, and hence, to the extent that forestal undertakings will allow, the weather can be controlled by human agency. The direct action of forests is an equalizing one; thus, especially in equatorial regions, and during the warmest portion of the year, they considerably reduce the mean temperature of the air. They also reduce the diurnal extremes of shade temperatures by altering the extent of radiating surface by evaporation, and by checking the movement of air, and while decreasing evaporation from the ground, they increase the relative humidity. Vegetation greatly diminishes the rate of flow-off of rain and the washing away of surface soil, and when a region is protected by trees, a steadier water supply is ensured, and the rainfall is better conserved. In regions of snowfall, the supply of water to rivers is similarly regulated, and without this and the sheltering influence of ravines and "gullies," watercourses supplied mainly by melting snow would be subject to alternative periods of flooding and dryness. This is borne out in the case of the inland rivers, the River Murray, for example, which has never been known to become dry, deriving its steadiness of flow mainly through the causes indicated.
(iii) Direct Influence of Forests on Rainfall. Whether forests have a direct influence on rainfall is a debatable question, some authorities alleging that precipitation is undoubtedly induced by forests, while others take the opposite view.

Sufficient evidence exists, however, to prove that, even if the rainfall has not increased, the beneficial climatic effect of forest lands more than warrants their protection and extension. Rapid rate of evaporation, induced by both hot and cold winds, injures crops and makes life uncomfortable on the plains, and, while it may be doubted that the forest aids in increasing precipitation, it must be admitted that it does check winds and the rapid evaporation due to them. Trees as wind-breaks have been successfully planted in central parts of the United States, and there is no reason why similar experiments should not be successful in many parts of the treeless interior of Australia. The belts should be planted at right angles to the direction of the prevailing parching winds, and if not more than half a mile apart will afford shelter to the enclosed areas.

In previous issues some notes on observations made in other countries were added (sce Official Year Book No. 6, pp. 86 and 95).

## § 3. Standard Times in Australia.

Prior to 1895 the official time adopted in the several colonies was for most purposes the mean solar time of the capital city of each.

In November, 1892, an intercolonial conference of surveyors was held in Melbourne to consider, among other things, the advantages of introducing the system of standard time. In this system it was proposed to make the initial meridian that of Greenwich, and to change local standard time by whole hours according to the longitude east or west of that of Greenwich. Thus for every difference of $15^{\circ}$ in longitude a change of one hour would be required. The minutes and seconds would then be identical everywhere.

To give effect to this proposal it was suggested that Australia should be divided into three zones, the standard times for which should be respectively the mean solar times of the meridians of $120^{\circ}, 135^{\circ}$ and $150^{\circ} \mathrm{E}$. longitude, thus giving standard times 8, 9 and to hours respectively, ahead of Greenwich time. It was proposed that the $120^{\circ}$ zone should comprise Western Australia, that the $135^{\circ}$ zone should comprise South Australia and the Northern Territory, and that the $150^{\circ}$ zone should comprise Queensland, New South Wales, Victoria and Tasmania.

The matter was also considered by several intercolonial postal conferences, and eventually in 1894 and 1895 legislation was enacted by each of the colonies in accord with the recommendations of the surveyor's conference of 1892 .

In 1898 the South Australian legislature amended its earlier provision, and adopted the mean solar time of the meridian $142^{\circ} 30^{\prime} \mathbf{E}$. longitude as the standard time for that colony, thus reducing the difference between the standard time of Adelaide and that of the capitals of the eastern colonies from an hour to half-an-hour, and forfeiting the great advantage of the system, viz., that the minutes and seconds should be identical throughout the world.

Particulars concerning these enactments are as follows :-
Standarn Times in Australia.

The standard time in the Australian Capital Territory is the same as in New South Wales.

Consequent upon the opening of the Trans-Australian Railway an arrangement has been made by which the change of time between South Australia and Western Australia (viz., $1 \frac{1}{2}$ hours) is divided into two changes of 45 minutes cach. Going east from Kalgoorlie the first change is made at Rawlinna, 235.18 miles out, where the time is put forward by 45 minutes. The second change of the same amount is made at Tarcoola, 794.05 miles out. Thenceforward South Australian standard time is kept. The advantage of standard time has thus been still further sacrificed, as there is not now even a whole half-hour difference; the essential idea of standard zone time has to this extent, therefore, been abandoned. The State Observatories at Sydney, Melbourne, Adelaide and Perth derive time by astronomical observation. By arrangement with the Australian Broadcasting Commission observatory time-signals are broadcast in the several States at intervals during the day. In addition, the Amalgamated Wireless (Australasia) Itd. re-broadcast the daily time-signals of certain overseas stations.

[^0]:    - Prepared from data supplied by the Commonwealth Metcorologist, W. S. Watt, Esquire.

[^1]:    * In Australia, artificial storage ponds or reservoirs are called " tanks."

[^2]:    16. Rainfall and Temperatures, Various Cities.-The following table shows rainfall and temperature for various important eities throughout the world, for the Australian Capital, and for the capitals of the Australian States.
[^3]:    (a) Not available.
    (b) $28 / 1923$ and $25 / 1924$.
    (c) 19/1924 and $24 / 1935$.
    (d) 1 and $3 / 1923$.
    (e) $1 / 1923,3 / 1924$, and 15 and $16 / 1931$. ( $f$ ) Total for year.
