Chapter 25 National Accounts

In Australia, there is a wide range of economic data available to analyse the performance of various components of the economy over time. For example, data are regularly published on the number of houses being built, the number of cars produced, whether employment is rising or falling, the composition of exports and imports and so on. While these and other statistical series are important in their own right, none of them in isolation can provide an overall picture of the state of the economy.

National accounts are designed to provide a systematic summary of national economic activity and have been developed to assist in the practical application of economic theory. At their summary level, the national income, expenditure and product accounts reflect the key economic flows of the Keynesian economic system: production, the distribution of incomes, consumption, saving and investment. At their more detailed level, they are designed to present a statistical picture of the structure of the economy and the detailed processes that make up domestic production and its distribution. The national accounts include many detailed classifications (for example, by industry, by purpose, by commodity, by State and Territory, and by asset type) relating to major economic aggregates.

The performance of the economy, as represented in national accounting measures such as growth in the national income or gross domestic product, is not an end in itself. Movements in gross domestic product at constant prices are an important measure of economic growth, but there is no single indicator which can describe all aspects of the well-being of a country's citizens.

There are significant aspects of the 'quality of life' which cannot be comprehended in a system of economic accounts, just as there are significant aspects of an individual's well-being which are not measured in the conventional concept (or any other concept) of that individual's income.

Notwithstanding their limitations, especially in relation to uses for which they were never designed, the national accounts provide vital information for a range of important purposes. The system of national accounts also provides a framework or structure which can be, and has been, adapted and extended to facilitate the examination of other economic and social policy issues.

A detailed presentation of the concepts underlying the national accounts is provided in the ABS publication Australian National Accounts: Concepts, Sources and Methods (5216.0).

The main output from the national accounts is a measure of the overall value of economic production in Australia in a given period, but without any double counting of the goods and services being produced. Many goods and services are bought by businesses for use in their own productive activities (for example, steel is bought by car manufacturers). If the value of all goods and services produced were simply added together there would be serious duplication because some goods and services would be added in several times at various stages of production. The overall measure of production, excluding double counting, is called gross domestic product, which is commonly referred to as 'GDP'. It is formally defined as:

the total market value of goods and services produced in Australia after deducting the cost of goods and services used up (intermediate consumption) in the process of production, but before deducting allowances for the consumption of fixed capital (depreciation).

Measurement of GDP

There are three ways of measuring GDP:

- The income approach, which measures GDP by summing the incomes accruing from production (wages, salaries and supplements; gross operating surplus (profits); and indirect taxes less subsidies).
- The expenditure approach, which involves summing all final expenditures on goods and services (that is, those goods and services which are not processed any further), adding on the contribution of exports and deducting the value of imports. Final expenditures consist of final consumption expenditure, gross fixed capital expenditure and increase in stocks. Exports are included in GDP because they are part of Australian production even though they are sold to overseas purchasers. Imports are deducted because, although they are included in final expenditures (for example, when someone buys an imported

video recorder its value is included as part of private final consumption expenditure) they are not part of Australian production.

• The production approach, which calculates GDP by taking the market value of goods and services produced by an industry (its gross output) and deducting the cost of goods and services used up by the industry in the productive process (intermediate consumption) which leaves the 'value added' by the industry (also called its gross product). GDP is then obtained by summing the gross product of all industries.

In theory, the three approaches result in identical estimates of GDP. In practice, because of the need to use different data sources for each method, the value of GDP obtained from each approach differs. The ABS refers to the above three alternative estimates of GDP as GDP(I), GDP(E) and GDP(P), respectively.

A fourth measure, the simple average of these three, referred to as GDP(A), is the preferred estimate of economic growth for Australia when expressed in constant price terms. Using movements in GDP(A) has been shown to provide a smoother and more reliable indicator of turning points in the economy than do changes in any of the individual measures of GDP. Quarterly changes in the constant price trend of GDP(A) are considered by the ABS to be the best indicator of short-term growth. Constant price data are published for all four estimates in original, seasonally adjusted and trend terms (see Constant price or 'real' GDP below).

25.1	GROSS DOMESTIC PRODUCT AT AVERAGE 1989-90 PRICES
	(\$ million)

Year	GDP(1)	GDP(E)	GDP(P)	GDP(A)
196263	126,915	127.532	127,710	127.386

Source: Australian National Accounts: National Income, Expenditure and Product (5204.0).

GDP(A) at average 1989–90 prices increased by 3.0 per cent in 1992–93, following a rise of

0.7 per cent in 1991–92. For some analytical purposes it is important to allow for the

impact of population growth on movements in GDP. Annual growth in GDP(A) per capita has been about 1.0 per cent to 1.8 per cent

lower than that for GDP(A) since 1971-72 and was negative in 1990-91 and 1991-92.

25.2 GDP(A) AND GDP(A) PER CAPITA

Constant price or 'real' GDP

The expenditure approach to calculating GDP measures Australian production by summing the amounts spent by the final users on the goods and services produced. However, by itself this is not always a good measure of production, since the value of a particular good or service is affected by inflation.

For example, the national accounts may show that the amount spent on motor cars is 20 per cent higher this year than it was last year. If the price of cars has increased by 20 per cent over the last year, then the number of cars bought will not have changed — expenditure has risen only because the price of cars has risen.

For a lot of uses, it is necessary to know how much physical production (for example, the number of cars made) has changed, rather than just the current (or dollar) value of production. Constant price estimates are the way in which this is achieved. They provide a measure, in dollar values, which indicates changes in the actual quantity of items produced or purchased. Because of this, constant price estimates of GDP are often referred to as estimates of 'real' GDP.

In essence, estimates of GDP at constant prices involve finding indicators of price changes in the items included in the national accounts, and using these to remove the effects of inflation from the estimates of GDP. Constant price estimates are expressed in terms of the average prices prevailing in a selected base year (currently 1989-90). Some of the main indicators used in this process are the component series from the consumer price index, which measures changes over time in the price of a 'basket' of goods and services bought by households. Other price indexes produced by the ABS (such as the import price index) are also used extensively in compiling the constant price estimates.

Implicit price deflators

A by-product of the calculation of constant price estimates is the implicit price deflator (or IPD). An IPD is the price index obtained when a current price estimate is divided by the corresponding constant price estimate. The ABS publishes a time series of IPDs for each of the expenditure side aggregates (excluding increase in stocks) in the domestic production account.

IPDs calculated from the major national accounting aggregates such as gross national expenditure are widely used as a broader measure of inflation in the economy than that available from any of the individual price indexes published by the ABS. However, care has to be taken in the interpretation of IPDs as they do not compare the price of a constant basket of goods between any two periods except when comparing the base period with another period. Therefore, they reflect a combination of the effects of actual price changes and changes in the composition of the aggregate from which the deflator is derived. An alternative set of price indexes, based on the expenditure side of the domestic production account, is fixed-weighted price indexes for the major expenditure aggregates. They measure the change in price of the basket of goods and services included in GDP in the proportions measured in 1989-90.

PRESENTATION OF THE AUSTRALIAN NATIONAL ACCOUNTS

National income, expenditure and product accounts

The Australian national income, expenditure and product accounts are compiled and published in some detail every quarter, in Australian National Accounts: National Income, Expenditure and Product (5206.0), and in greater detail once a year, in Australian National Accounts: National Income, Expenditure and Product (5204.0).

Domestic production account. T h e domestic production account indicates changes

in Australian production over time. Table 25.4 shows that, in 'real' terms (that is, after the effects of inflation are removed from the dollar value of Australia's production) there was a fall in production during the 1990–91 financial year. However, the two years since the recession in 1990–91 have both shown moderate growth, although growth in 1991–92 was relatively low, it accelerated in 1992–93 with growth of approximately three per cent in that year.

The domestic production account can also be used to show changes in the share of income accruing to labour (that is, wages, salaries and supplements) compared with the share accruing to capital (that is, profits). Graphs 25.5 and 25.6 show how the shares of each of wages and profits (defined as the gross operating surplus of private corporate trading enterprises) to GDP(I) at factor cost have changed since 1962–63.

The highest recorded value of the wages share of GDP(I) at factor cost is 63.4 per cent in 1974-75. The wages share has recovered somewhat from its recent low value of 55.4 per cent in 1988-89, but remains at a relatively low level compared with most of the 1970s and early 1980s.

The profits (GOS of private corporate trading enterprises) share of GDP(I) at factor cost reached its highest recorded value in 1984–85 (17.2%), slightly above the most recent high value of 17.1 per cent in 1988–89. Although the ratio fell to 15.8 per cent in 1991–92, it rose to 16.1 per cent in 1992–93, and is at a relatively high level by past standards.

National income and outlay account. The national income and outlay account shows how much of the national income is spent on final consumption. That part of income which is not spent in this way is saving.

740 Year Book

Household saving as a percentage of GDP(I) increased significantly between 1962–63 and 1974–75, but has fallen subsequently from its high of 9.9 per cent in 1974–75 to 3.2 per cent in 1992–93. General government saving has fallen for the fourth consecutive year as a percentage of GDP(I)

(-3.8% in 1992-93); in current value terms it was -\$15.5 billion in 1992-93. Saving of corporate trading enterprises has been negative for 16 of the past 19 years. In 1992-93 it was -0.2 per cent of GDP(1) (-\$1.2 billion in current value terms).

Source: Australian National Accounts: National Income, Expenditure and Product (5204.0).

National capital account. The national capital account shows how the saving from the national income and outlay account is used to finance gross fixed capital expenditure. If, as is currently the case in Australia, the nation's saving is not sufficient to pay for all

the capital equipment needed for Australian production, the shortfall must be borrowed from overseas. The amount borrowed from overseas is shown in the national capital account as a negative entry for net lending to overseas.

Australia

25.10 INVESTMENT, BY SECTOR, SHARE OF GDP(I)

As a proportion of GDP(I), investment by corporate trading enterprises fell to very low levels during the 1970s and then rose to a peak of 12.4 per cent in 1986–87. It has subsequently fallen fairly steadily to 9.2 per cent in 1992–93. Household investment as a proportion of GDP(I) has fallen from 9.6 per cent in 1988-89 to 7.4 per cent in 1992-93. While general government investment as a proportion of GDP(I) peaked at 4.4 per cent in 1975-76, it has fallen steadily since then and is now 2.2 per cent of GDP(I).

25.12 OVERSEAS TRANSACTIONS ACCOUNT (\$ million)

744 Yean Boooks

The household sector has been a lender to the other sectors in the economy for all years except 1967–68. As a proportion of GDP(I), lending by households in recent years has risen from 0.3 per cent in 1988–89 to 1.4 per cent in 1992–93. Borrowing (that is, negative net lending) by corporate trading enterprises has fluctuated significantly over the whole period from 1962–63 to 1992–93. However, there is no discernible increasing or decreasing trend as a proportion of GDP(I). After being a net lender for the period 1987–88 to 1989–90, general government has returned to being a significant borrower over the past three years.

Overseas transactions account. The overseas transactions account is actually derived from the detailed balance of payments

current account — see Chapter 26. It shows Australia's exports and imports, incomes received by Australian residents from overseas, and incomes paid to overseas by Australian residents. The balance is net lending to overseas.

Australia has generally been a net borrower of capital from overseas. In the national accounts, this situation is reflected by a negative value for 'net lending to overseas'. Following one year where Australia actually loaned money to overseas in the early 1970s, net borrowing from overseas, expressed as a proportion of GDP(I), increased rapidly during the 1970s and has remained at relatively high levels since the early 1980s. The following graph shows this proportion since 1962–63.

Source: Australian National Accounts: National Income, Expenditure and Product (5204.0).

746 Year Book Australia

The importance of foreign trade to the Australian economy is illustrated by the following graph, which shows the ratios of exports and imports of goods and services to GDP(I) for the financial years 1962–63 to 1992–93. In 1992–93 the import ratio was

19.0 per cent and the export ratio was 18.4 per cent. For a detailed discussion about a wide range of balance of payments ratios refer to *Balance of Payments, Australia,* 1991-92 (5303.0).

Source: Australian National Accounts: National Income, Expenditure and Product (5204.0).

State accounts

As well as Australia's national accounts, the ABS produces State accounts each quarter. These provide quarterly estimates of gross State product and State final demand. Gross State product is produced by summing the incomes generated in the production process (the income approach to measuring total production). At present, estimates of gross State product are only in current prices. State final demand is equal to the sum of private and government final consumption expenditure and gross fixed capital expenditure. Estimates of State final demand are available in both current and constant prices.

An important use of State accounts is to compare the performance of each State and

Territory. The following graphs show gross State product, in current prices, per head of mean population for each State and Territory divided by the Australian value (GDP(I) per head of mean population) since 1980–81.

Gross State product per head of mean population in 1992–93 was above the national average in New South Wales, Victoria, Western Australia, the Northern Territory and the Australian Capital Territory. GSP per head of mean population has been below the national average for the whole length of the time series (that is, since 1980–81) in each of Queensland, South Australia and Tasmania.

The only States to experience a decline in this ratio in 1992–93 were New South Wales, Tasmania and the Northern Territory.

25.15 GROSS STATE PRODUCT PER HEAD OF MEAN POPULATION (Australia = 100.0)

Input-output tables

Basic structure of input-output tables.

Input-output tables show the structure of a country's entire production system for a particular period, usually one year. They show which goods and services are produced by each industry and how they are used (for example, some goods, such as cars, are sold to final consumers while others, such as steel, are used as inputs by other industries in producing more goods and services). The tables are based on the principle that the value of the output of each industry can be expressed as the sum of the values of all the inputs to that industry plus any profits made. All the goods and services produced in a period are identified as being used as inputs by industries in their production process, being sold to final users of the goods and services (either in Australia, or overseas as exports), or contributing to the change in stocks (an increase in stocks if more goods are produced than purchased or a run-down in stocks if purchases exceed production). For the production system as a whole, the sum of all outputs must equal the sum of all inputs and for the economy as a whole, total supply must equal total demand (stocks provide the mechanism which balances supply and demand).

Relationship to the national income and

expenditure accounts. Input-output tables can be directly related to the domestic production account. The income side of the domestic production account shows the amount of income generated in the economy accruing to labour (in the form of wages, salaries and supplements) and to capital (as profits or, in national accounting terms, 'gross operating surplus'). The expenditure side of the account shows the value of goods and services entering into the various categories of final demand.

The input-output tables provide a much more detailed disaggregation of the domestic production account than is available in the national income, expenditure and product accounts. The latter only supply details of the end results of economic activity, whereas the input-output tables provide a means of tracing flows of goods and services step by step through the production process. The extra detail provided by the input-output tables is essential for many analyses. **7-sector input-output table.** The following table and diagram show the flows of goods and services in respect of 1989–90.

The links between the table and the diagram are explained by working through the following formulas.

Intermediate usage (\$296,957 million) in the diagram is derived by summing from column 8 of the table — Intermediate usage (\$260,666 million); Sales by final buyers (\$833 million); Competing imports (\$34,005 million); and Complementary imports (\$1,453 million).

Gross value added (\$375,511 million) in the diagram is derived by summing from column 14 of the table — Wages, salaries, and supplements (\$172,529 million); Gross operating surplus (\$158,551 million); and taxes: Commodity taxes (net) (\$24,010 million), Indirect taxes n.e.c. (net) (\$16,979 million) and Duty on competing imports (\$3,442 million).

Domestic production (\$672,468 million) in the diagram is derived by summing Intermediate usage from column 8 of the table (\$260,666 million); total final demand at basic values from column 13 (\$392,307 million); and the indirect taxes payable on those final demand items (*see* column 13): Commodity taxes (net) (\$14,882 million), Indirect taxes n.e.c. (net) (\$2,617 million) and Duty on competing imports (\$1,996 million).

Imports (\$67,835 million) in the diagram is derived by summing from column 14 of the table — Competing imports c.i.f. (\$65,660 million) and Complementary imports c.i.f. (\$2,175 million).

Total supply (\$740,303 million), which must be equal to Total Demand, is the sum of Domestic production (\$672,468 million) and Imports (\$67,835 million).

Domestic final demand (\$382,489 million) in the diagram is derived from the table by subtracting total Exports (\$60,857 million), column 12, from total Final demand (\$443,346 million), column 13.

Exports (\$60,857 million) in the diagram is total Exports, column 12, in the table.

Total Demand (\$740,303 million) is the sum of Domestic final demand (\$382,489 million), Intermediate usage (\$296,957 million), and Exports (\$60,857 million).

25.17 THE AUSTRALIAN ECONOMY, FLOW OF GOODS AND SERVICES (a) (\$ million)

(a) Flows are based on 1989-90 Input-Output tables. (b) Includes re-exports Source: Derived from Australian National Accounts: Input-Output Tables (5209.0).

Financial accounts

In addition to the national accounts, the ABS produces quarterly information on the level of financial assets and liabilities of each institutional sector of the economy, the market for financial instruments and inter-sectoral transactions in financial assets and liabilities classified by financial instrument — see Chapter 23.

Further developments in Australia's national accounts

Environmental satellite accounts. T h e 1993 System of National Accounts (SNA) recommends the development of a system of environmental satellite accounts designed to enable the adjustment of GDP to take account of the depletion of natural resources and the degradation of the environment as a result of economic activity. International standards for environmental accounting are being developed and the ABS is monitoring the development of these standards with the ultimate aim of developing a system of environmental satellite accounts for Australia at some time in the future.

The value of unpaid work. Not all production that occurs in an economy is recorded in the national accounts. For example,

the value of unpaid work, particularly unpaid work in the home and volunteer work, is excluded in accordance with prevailing international statistical standards. There is considerable interest, however, in the contribution of unpaid work to the economy and the 1993 SNA has recommended that the value of this work should be shown in satellite accounts.

Although it can be argued that unpaid household work comes within the definition of economic production, it has been excluded from the scope of GDP as defined by the SNA. This is because the major focus of the national accounts is on changes in the economic market sector. There are also significant conceptual problems and practical difficulties associated with the availability of data and the selection of appropriate shadow prices.

The ABS has produced a series of estimates of the value of unpaid household work based on different assumptions about the prices that could be assigned to value the various activities. The estimates were based on the results of the 1992 national Time Use Survey. Using the ABS preferred valuation method (individual function replacement cost method) unpaid work in 1992 was estimated to be 58 per cent of GDP.
