EXPLANATORY NOTES

Introduction

In August 1980 a sample household survey, based on the population survey, was conducted throughout Australia in order to obtain information about the weekly earnings of wage and salary earners. For the sake of brevity, wage and salary earners are referred to in the tables as "employees".

2. Some results of the survey were published on 19 December 1980 in Weekly Earnings of Employees (Distribution), August 1980 (Preliminary), (6309.0).

The population survey

3. The survey was based on a multi-stage area sample of private dwellings (about 30,000 houses, flats, etc.) and non-private dwellings (hotels, motels, etc.) and covered about two-thirds of one per cent of the population of Australia. The information was obtained from the occupants of selected dwellings by carefully chosen and specially trained interviewers, the interviews being conducted during the two weeks beginning on 11 August 1980.

Scope

- 4. The estimates relate to all persons aged 15 years and over who were employed as wage and salary earners in their main job, except:
 - (a) members of the permanent defence forces,
 - (b) certain diplomatic personnel of overseas governments, customarily excluded from census and estimated populations,
 - (c) overseas visitors holidaying in Australia,
 - (d) members of non-Australian defence forces (and their dependants) stationed in Australia,
 - (e) patients in hospitals and sanatoria or inmates of gaols, reformatories, etc., and
 - (f) persons on workers' compensation.

Interpretation of results

- 5. Since the estimates are based on a sample, they are subject to sampling variability. (See Technical note, page 20, for further details.) In addition, they are subject to errors of response and reporting. In many cases the answer to the question on earnings was based on the knowledge of one person (generally the housewife). It is considered that there may be some understatement in the estimates because of imperfect recall of minor or irregular sources of earnings. Other errors may be due to genuine misunderstanding.
- 6. Other points which should be kept in mind in interpreting the results of this survey are as follows:
 - (a) In making comparisons of earnings between groups of employees it must be remembered that there will be differences arising from the different age and occupation structures of these groups. This is particularly important, for

- example, when interpreting results in Tables 8, 9 and 14, which show earnings according to birthplace.
- (b) Because employers and self-employed persons were excluded from the survey the results should not be taken as representative of the earnings of all employed persons. In particular, earnings of employees in some occupation groups in Tables 9, 11 and 12 may not reflect the earnings of all persons in those occupations.

Definitions

- 7. Weekly earnings refers to gross weekly wages and salaries (i.e. before taxation and other deductions have been made). For persons paid other than weekly, earnings were converted to a weekly equivalent.
- 8. Median weekly earnings is the amount which divides the distribution of individuals into two equal groups, one having earnings above and the other below that amount. Medians were calculated from grouped data, the class intervals in some cases being finer than those published in the tables. Linear interpolation was used within the class interval in which the median fell.
- 9. Mean weekly earnings is the amount obtained by dividing the total earnings of a group by the number of units in that group.
- 10. The main job was defined as the job at which most hours were worked during the survey week (i.e. the week before the interview week). The second job was defined to include all remaining jobs, in which some hours were worked during the survey week. A person who held more than one job as an employee was classified to the industry and occupation of the main job.
- 11. Hours paid for refers to the number of hours for which an employee was paid and not necessarily to the number of hours actually worked (e.g., an employee on paid leave for the week was asked to report the number of hours for which he was paid).
- 12. Hours worked refers to actual hours worked during the survey week, not necessarily hours paid for. Thus, if a person had been on leave for the whole week, hours worked would have been recorded as nil.
- 13. Full-time employees are those who usually work 35 hours a week or more (in all jobs) and others who, although usually part-time employees, worked 35 hours or more during the survey week. It should be noted that some full-time employees may have worked or been paid for less than a full week. Part-time employees are those who usually work less than 35 hours a week and who did so during the survey week. When recording hours of work, fractions of an hour were disregarded.
- 14. For the purposes of the survey persons were classified as having a second job if, during the survey

week, they:

- (a) worked in a second job; and
- (b) were employed as a wage or salary earner in both of their jobs.

Service in the reserve defence forces was not regarded as a second job. Persons who by the nature of their employment worked for more than one employer, e.g. domestics, odd-job men, baby-sitters, etc., were not counted as multiple jobholders unless they also held another job of a different kind; nor were those who worked for more than one employer solely by reason of changing jobs during the survey week.

15. For a detailed description of industries shown in Tables 4 and 10 refer to Australian Standard Industrial Classification (ASIC), 1978 Edition, Volume 1 – The Classification (1201.0).

Comparability of estimates with those for previous years

- 16. Similar surveys have been conducted annually since August 1975. However, care must be taken in making comparison from one survey period to another as the 1975 survey data related to earnings from all jobs and hours worked, whereas subsequent survey publications contain tables on earnings from the main job as well as all jobs and statistics of hours paid for as well as hours worked.
- 17. The 1978, 1979 and 1980 survey estimates are based on revised population benchmarks, derived from the 1976 Population Census, adjusted for underenumeration. Estimates of numbers of employees in these surveys are therefore not compatible with those from earlier surveys. Because of resource constraints it is not feasible to calculate estimates on the revised basis for earlier years. However, it is considered that the estimates of mean and median earnings would have been only slightly affected by the change.
- 18. Industry estimates from the 1980 survey have been classified according to the 1978 version of ASIC. (See paragraph 15.) Estimates from previous surveys were classified according to the 1969 classification. The main industries affected by the change are mining; manufacturing; and finance, property and business services. Although estimates for these industries are not strictly comparable with corresponding industries for previous surveys, the effect of the change is likely to be very small, particularly for estimates of mean and median earnings.

Reliability of the estimates

19. Since the estimates in this publication are based on information obtained from occupants of a sample of dwellings, they may differ from the figures that would have been produced if the information had been obtained from occupants of all dwellings. An indication of the likely differences is given in the Technical note, page 20. See also paragraph 12 of the Technical note regarding non-sampling errors.

⁽a) Includes permanently separated and de facto relationships. (b) Never married, widowed and divorced. (c) Since part-time employees are defined as those who usually work less than 35 hours and who did so during the survey week, these figures may include school teachers, academic staff in universities, aircrew, etc.

815		

⁽a) According to the classification of occupations used for the 1976 Population Census.

NOTE. Care should be exercised in interpreting the estimates in this table, for the following reasons: (a) The estimates relate only to employees aged 20 years and over. Employers and self-employed persons are therefore excluded. (b) Because particulars of educational qualifications were not obtained in the survey the information on occupations cannot be checked, and for certain groups, especially Professional, Technical and Related Workers (001 - 091), may be subject to misreporting. (c) Some occupation groups shown cover a variety of activities. (d) The estimates are subject to sampling variability. See Technical Note, paragraphs 5 and 6.

NOTE. See page 2, paragraph 6(a) and Technical Note, paragraphs 5 and 6, regarding interpretation of the figures in this table.

TECHNICAL NOTE

Estimation procedure

Estimates derived from the survey are obtained by using a complex ratio estimation procedure, which ensures that the survey estimates conform to an independently estimated distribution of the population by age and sex, rather than to the age and sex distribution within the sample itself.

Reliability of the estimates

- Since the estimates in this publication are based on information obtained from occupants of a sample of dwellings they are subject to sampling variability; that is, they may differ from the figures that would have been produced if all dwellings had been included in the survey. One measure of the likely difference is given by the standard error, which indicates the extent to which an estimate might have varied by chance because only a sample of dwellings was included. There are about two chances in three that a sample estimate will differ by less than one standard error from the figure that would have been obtained if all dwellings had been included, and about nineteen chances in twenty that the difference will be less than two standard errors. Another measure is the relative standard error, which expresses the standard error as a percentage of the estimate.
- 3. Space does not allow for the separate indication of the standard error of all estimates in this publication. Table A shows standard errors of estimates of numbers of employees for a range of estimate sizes, while Table B shows relative standard errors of estimates of mean and median earnings for different numbers of employees. These figures will not give a precise measure of the standard error of a particular estimate, but they will provide an indication of its magnitude.
- 4. An example of the use of Table A is as follows: Table 2 shows that the estimated number of male full-time employees in Australia whose weekly earnings were between \$140 and \$150 was 66,100. Table A shows the standard errors of Australian estimates of 50,000 and 100,000 to be 2,900 and 3,900 respectively. By interpolation the standard error of an estimate of 66,100 is approximately 3,300. Therefore there are about two chances in three that the number of employees whose weekly earnings were between \$140 and \$150 would be between 62,800 and 69,400, and about nineteen chances in twenty that the number would be between 59,500 and 72,700, if all dwellings had been included in the survey.
- 5. The procedure for obtaining the standard error of an estimated mean or median is as follows: from the table containing the mean or median obtain the number of employees to which it refers, from Table B obtain the percentage standard error appropriate to that number, interpolating where necessary, and apply this percentage to the estimated mean or median. If the estimate relates to part-time employees the standard error should be multiplied by 2 for males and 1.4 for females and persons.

- 6. An example of the use of Table B is as follows: Table 2 shows the mean weekly earnings of all female full-time employees in Australia as \$193, and the number of such employees as 1,288,400. Table B shows the relative standard errors of estimates based on 1,000,000 and 1,500,000 employees to be 0.64 per cent and 0.52 per cent respectively. By interpolation the relative standard error of the estimate is about 0.58 per cent, or \$1.10 (0.58 per cent of \$193). Therefore there are about two chances in three that the mean weekly earnings of female full-time employees would fall within the range \$191.90 to \$194.10, and about nineteen chances in twenty that they would fall within the range \$190.80 to \$195.20, if all dwellings had been included in the survey.
- 7. As the standard errors in the tables show, the smaller the estimated number of employees the higher is the relative standard error. Very small estimates are thus subject to such high standard errors (relative to the size of the estimate) as to detract seriously from their value for most reasonable uses. In this publication estimates below the levels shown in Table A, and means and medians based on such estimates, have not been included. Although figures for numbers of employees can in some cases be derived by subtraction they should not be regarded as reliable.
- 8. The reliability of an estimated percentage, computed by using sample data for both numerator and denominator, depends upon both the size of the numerator and the size of the denominator. However, the relative standard error of the estimated percentage will generally be lower than the relative standard error of the estimate of the numerator. The relative standard errors of the numerators can be obtained from Table A.
- The procedure for obtaining approximate standard errors of percentages is shown by the following example: in Table 9 the percentage of Australian-born male full-time employees in clerical occupations is shown as 10.8 and the numerator (i.e. the number of such employees) as 238,400. By interpolation from Table A the standard error of the numerator is approximately 5,500; the relative standard error is therefore 2.3 per cent (since 5,500 is 2.3 per cent of 238,400). The standard error of the percentage in clerical occupations is therefore approximately 2.3 per cent of 10.8, i.e. 0.2. Thus there are about two chances in three that the percentage that would have been obtained if all dwellings had been included in the survey is in the range 10.6 to 11.0 per cent and about nineteen chances in twenty that it is in the range 10.4 to 11.2 per cent.
- 10. Published figures may also be used to estimate the difference between two survey estimates (estimates of numbers, means, medians and percentages). Such figures are themselves estimates and therefore subject to sampling error. The sampling error of the difference between two survey estimates depends on the standard

errors of the original estimates and on the relationship (correlation) between the estimates. An approximate standard error of the difference between two estimates (x-y) may be calculated by the following formula:

Standard error (x-y) =
$$\sqrt{\text{Standard error (x)}}^2 + \{\text{Standard error (y)}\}^2$$

While this formula will be exact only for differences between separate and uncorrelated (unrelated) characteristics or sub-populations, it is expected to provide a good approximation for all differences likely to be of interest in this publication.

11. An example of the use of the above formula is as follows: Table 2 shows that for full-time employees the difference between the estimates of the mean weekly earnings of all married females and all not married females was \$29 (\$208 - \$179). By using the procedure outlined in paragraph 5 the standard errors of the two original estimates can be approximated as \$1.70 and

\$1.40 respectively. Therefore the standard error of the difference of \$29 is $\sqrt{(\$1.70)^2 + (\$1.40)^2}$, or \$2.20 (rounded to the nearest 10 cents). Therefore there are about two chances in three that the difference that would have been obtained if all dwellings had been included in the survey is between \$26.80 to \$31.20 and about nineteen chances in twenty that it is between \$24.60 and \$33.40.

12. The imprecision due to sampling variability, which is measured by the standard error, should not be confused with inaccuracies that may occur because of imperfections in reporting by interviewers and respondents. Inaccuracies of this kind are referred to as the non-sampling error, and they may occur in any enumeration, whether it be a full count or only a sample. Every effort is made to reduce the non-sampling error to a minimum by careful design of questionnaires, intensive training and supervision of interviewers and efficient operating procedures. See page 2, paragraph 5.
